Measuring productivity change in higher education: an application of Hicks-Moorsteen total factor productivity index to Malaysian public universities

Abstract

This paper offers an in-depth analysis of efficiency and productivity changes using the Hicks-Moorsteen total factor productivity index, in the context of higher education institutions. Unlike the Malmquist method, this approach makes no assumptions about firms' returns to scale conditions. We assume that the production technology exhibits variable returns to scale, which is more plausible than the constant returns to scale assumption, because universities usually operate at suboptimal scales. Three major groupings of Malaysian public universities are used in our case study: research, comprehensive, and focused universities. The results show that technical efficiency has improved after the 2007 National Higher Education Strategic Plan within all the three university groupings.

Abstract

This paper offers an in-depth analysis of efficiency and productivity changes using the Hicks–Moorsteen total factor productivity (TFP) index, in the context of higher education institutions. Unlike the Malmquist method, this approach makes no assumptions about firms' returns-to-scale conditions. We assume that the production technology exhibits variable returns to scale, which is more plausible than the constant returns to scale assumption, because universities usually operate at suboptimal scales. Three major groupings of Malaysian public universities are used in our case study: research, comprehensive, and focused universities. The results show that technical efficiency has improved after the 2007 National Higher Education Strategic Plan within all the three university groupings.

1 Introduction

The Malmquist productivity index is considered the most appropriate tool for measuring changes in efficiency and productivity of firms. Johnes (2008), Worthington, and Lee (2008), Agasisti and Johnes (2009), and Bradley et al. (2010) are among the most recent studies to have applied this useful tool. Despite its evident popularity, however, there has also been

extensive discussion of the arguments for and against using constant returns to scale (CRS) to estimate Malmquist indices. Grifell-Tatje and Lovell (1995) and O'Donnell (2012a) argue that with non-constant returns to scale, the Malmquist index is not able to measure productivity change precisely. This bias is systemic, and depends on the magnitude of scale economies (Coelli and Rao 2005). Ray and Desli (1997) and Wheelock and Wilson (1999) argue that when a firm's location (from one period to another) remains unchanged, and the changes in scale efficiency are only related to a shift in the variable returns to scale (VRS) estimate of technology, there will be no resulting technical change under CRS. Hence, the resulting CRS estimate of technology may be statistically inconsistent. Consequently, Wheelock and Wilson (1999) state that the popular decomposition of the Malmquist index conducted by Färe et al. (1994) is also problematic.

In order to avoid the above problem, O'Donnell (2012a) proposes a new approach to decompose the “multiplicatively complete” TFP indices (those that can be presented in terms of aggregate inputs and aggregate outputs) into technical change and different measures of efficiency change. O'Donnell does this without making any assumptions about the optimizing behaviour of firms, their market structure, or returns to scale for a multiple-input, multiple-output case. O'Donnell (2012a) also proves that the group of complete TFP indices include the Fisher, Konus, Törnqvist, and Hicks–Moorsteen indices, but not the Malmquist index.

In the context of the higher education system, because universities are not operating at optimal scale and they face imperfect competition, the new decomposition of the Hicks–Moorsteen TFP index can be utilized, allowing us to analyze changes in the productivity of firms under the VRS assumption. Although extensive research has been carried out on the productivity of higher education institutions, no single study has investigated TFP of universities under the VRS assumption. Another advantage of the use of the Hicks–

Moorsteen TFP index is that it reduces the possibility of producing infeasible results (Epure et al. 2011).¹ In addition, in their recent comprehensive comparison of the Malmquist index and Hicks–Moorsteen index, Kerstens and Van de Woestyne (2014, p.756) clearly state: “As to the question whether the Malmquist and Hicks–Moorsteen indices are empirically indistinguishable or not, the differences between both primal productivity indices turn out to be significantly different for all flexible returns to scale technology specifications.” Kerstens and Van de Woestyne (2014, p.756) recommend that “if one wants to be on the safe side, then one conclusion is that in case the interest centers on TFP measurement it is probably wise to immediately opt for the Hicks–Moorsteen index.” Based on the above evidence, this study uses the Hick-Moorsteen index to analyze the performance of universities. To the best of our knowledge, this study is the first employing this index in the area of higher education.

The Malaysian public higher education sector is used as a case study mainly because in the last decade the Malaysian government has emphasized productivity improvement in the public higher education sector, in recognition of its role as an engine for promoting the development of quality human capital. Overall, Malaysia is keen to be recognized as a major hub for higher education in the region and has launched policies for supporting the internationalization and improving the teaching and learning quality, together with enhancements of research and competition in the sector. This sector, therefore, has undergone some fundamental changes, which have led to its rapid expansion over the last decade. In particular, the implementation of the NHESP (National Higher Education Strategic Plan, “the plan”) in 2007 was the most important policy change in this area. Kaur and Sirat (2010) argue that this plan is Malaysia’s key policy initiative in revolutionizing and transforming higher education. As part of this plan, the government raised the share of research and development in gross domestic product (GDP) from 1.5% to 4.9%, with public universities being the

recipients of these national research and development funds (Malaysian Ministry of Higher Education 2007). Despite the large allocation of funds into the sector, however, there has been no empirical study of the effect of the plan on the performance of public universities. This study, therefore, uses the Hicks-Moorsteen TFP index under VRS and a four-year panel dataset (2006 to 2009) to evaluate productivity changes of Malaysian public universities.

The remainder of this paper is structured as follows. Section 2 presents a brief literature review of the related studies on the efficiency and productivity changes in the area of higher education. Section 3 discusses the Hicks–Moorsteen TFP index and its decompositions. Section 4 describes the data employed and the input and output classifications. Section 5 presents our empirical results, followed by some concluding remarks in Section 6.

2 Literature review

There has been a rapid expansion during the last few decades in the use of nonparametric approaches in measuring the efficiency and productivity changes of higher education institutions. A large number of these studies have been undertaken in developed countries (e.g. Athanassapoulos and Shale 1997; Abbott and Doucouliagos 2003; Emrouznejad and Thanassoulis 2005; Johnes 2006). Only a few of the higher education studies pertain to developing countries. For instance, Ng and Li (2000) examine the efficiency of 84 key Chinese higher education institutions in the post-reform period (1993–1995) using data envelopment analysis (DEA). Focusing on the research performance of these universities, they found that their performance has, on average, improved over time. In another study of developing countries, Cokgezen (2009) investigates the technical efficiency of faculties of economics in Turkey in 2004. The results indicate an overall low level of efficiency with some variations across the faculties.

Focusing mainly on efficiency estimates may lead to an incomplete view of the performance of universities over time. Changes in distance function values may occur over time due to two reasons: 1) efficiency changes (the movement of universities within the input–output space); or 2) technological changes (the changes of the boundary of the production set). The decomposition of the TFP indices (such as the Malmquist index) makes it possible to distinguish between changes in efficiency, productivity, and technological changes. However, only a small, but growing, number of studies have so far attempted to use the Malmquist index for this purpose, among them, Flegg et al. (2004), Carrington et al. (2005), Johnes (2008), Worthington and Lee (2008), Agasisti and Johnes (2009), and Bradley et al. (2010). Most of these studies have found productivity progress in different sectors, but this is mainly attributed to changes in technology and/or efficiency. For example, Flegg et al. (2004) examine changes in the productivity of 45 British universities during the period 1980–1993 and show that positive variations in productivity were due to technological change, rather than efficiency change. In a study of 35 Australian universities, Worthington and Lee (2008) also identify similar results in productivity growth. Agasisti and Johnes (2009) provide cross-country efficiency and productivity comparisons of English and Italian universities over a four-year period (2002–2005), attributing the overall productivity progress in each country to technological improvements and efficiency growth, respectively. Bradley et al. (2010) investigate 200 further education providers in UK during the period 1999–2003. Their results show that the sector’s productivity growth stems from both technical efficiency and technological changes.

Despite the growing literature associated with the application of the conventional Malmquist index, little is documented about the application of the Hicks–Moorsteen index. Some of the main applications of this index are O’Donnell (2010a; 2012a; 2012b) in the

context of the agricultural sector, Simões and Marques (2012) in the waste sector and Epure et al. (2011), and Arjomandi (2012; 2014) in the banking sector.

3 Hicks–Moorsteen TFP index and its components

Considering a firm with multiple inputs and outputs, according to Jorgenson and Griliches (1967) and Good et al. (1997), TFP can be defined as $TFP_{nt} = Y_{nt}/X_{nt}$, where Y_{nt} and X_{nt} are, respectively, the aggregate output and aggregate input of the n^{th} firm in period t . Based on this definition, we may specify TFP changes as being the ratio of an output quantity index to an input quantity index. O'Donnell (2012a) refers to such index numbers as multiplicatively complete. Among the multiplicatively complete indices, the Hicks–Moorsteen TFP index is the only one that can be estimated without requiring price data. This index is in fact a ratio of Malmquist output and input quantity indices, which is based on the works of Hicks (1961) and Moorsteen (1961):

$$TFP_{HM}^{t,t+1} = \left(\frac{D_o^{t+1}(x^{t+1}, y^{t+1})D_o^t(x^t, y^{t+1})}{D_o^{t+1}(x^{t+1}, y^t)D_o^t(x^t, y^t)} \frac{D_I^{t+1}(x^t, y^{t+1})D_I^t(x^t, y^t)}{D_I^{t+1}(x^{t+1}, y^{t+1})D_I^t(x^{t+1}, y^t)} \right)^{1/2} \quad (1)$$

In Equation 1, $D_o(x, y)$ and $D_I(x, y)$ are output and input distance functions, respectively, defined as $D_o^T(x, y) = \min\{\delta > 0 : (x, y/\delta) \in P^T\}$, and $D_I^T(x, y) = \max\{\rho > 0 : (x/\rho, y) \in P^T\}$, where P^T is the period T production possibilities set.² These distance functions can be calculated using Data Envelopment Analysis (DEA) models developed by O'Donnell (2012a). DEA does not necessitate any restrictive assumptions regarding the functional form and efficiency distribution. It must be noted, however, that DEA has its own limitations as it makes no allowance for statistical noise, and hence one should be cautious in the interpretation of the results. Because of this statistical shortcoming, any possible measurement errors in the data could make the estimated efficiency and TFP components to some extent biased. One way to

quantify the magnitude of the possible errors is to estimate the technology using an econometric methodology, such as stochastic frontier analysis, which allows for statistical errors. However, the use of such an approach is not possible in this paper as there are only 17 observations per year, one for each university. Notwithstanding these possible shortcomings, we perceive that the potential risks associated with using a DEA-based Hicks-Moorsteen TFP index are outweighed by the potential benefits and valuable insights that this advanced technique can provide us.

The output-oriented decomposition of a multiplicatively complete TFP index for firm n in period t can be rewritten as:

$$TFP_{nt} = TFP_t^* \times (OTE_{nt} \times OME_{nt} \times OSE_{nt}) \quad (2)$$

Where TFP_t^* is the maximum TFP possible using any technically feasible inputs and outputs; OTE_{nt} (output-oriented technical efficiency) measures the difference between observed TFP and the maximum TFP that is possible while holding the input-output mix and input level fixed; OME_{nt} (output-oriented mix efficiency) measures the change in productivity when restrictions on the input and output mix of the firm are relaxed; and OSE_{nt} (output-oriented scale efficiency) measures the difference between TFP at a technically and mix efficient point and TFP at the point of optimum productivity.

The interpretation of efficiency measures is straightforward. A technical efficiency estimate of unity indicates that the firm lies on the boundary of the production set, and as such, the corresponding firm is said to be relatively efficient. On the other hand, an estimated value below unity shows that the firm is positioned under the frontier and is relatively

inefficient. A firm with technical efficiency equal to unity, but with scale and mix efficiencies less than unity, is still on the frontier, but at a relatively unproductive point.

A similar equation to Equation 2 can be formulated for any other firm like m in period s . Accordingly, the index number that compares the TFP of firm n in period t with the TFP of firm m in period s can be written as:

$$TFP_{ms,nt} = \frac{TFP_{nt}}{TFP_{ms}} = \underbrace{\left(\frac{TFP_t^*}{TFP_s^*} \right)}_{\text{Technical changes}} \times \underbrace{\left(\frac{OTE_{nt}}{OTE_{st}} \times \frac{OME_{nt}}{OME_{st}} \times \frac{OSE_{nt}}{OSE_{st}} \right)}_{\text{Efficiency changes}} \quad (3)$$

The term included in the first parentheses on the right-hand side of this equation represents technical changes, measuring the difference between the maximum TFP possible using any technology feasible at times t and s . Hence, the sector experiences technical improvement or decline, depending on whether TFP_t^*/TFP_s^* is greater or less than 1. Unlike in the decomposition of the Malmquist index of Färe et al. (1994), the technical change in Equation 3 contains a mixed effect, and characteristically varies from firm to firm. The three other ratios on the extreme right-hand side of Equation 3 are various components of technical-efficiency changes and are referred to as measures of technical-efficiency change, mix-efficiency change, and scale-efficiency change. We used the DPIN software written by O'Donnell (2010b) to estimate different measures of efficiency and TFP components.

4 The data

This study utilizes a four-year panel dataset (2006–2009) for analysing the performance of 17 Malaysian public universities in the years before and after the implementation of the NHESP. The sector consists of 20 public universities, which are categorized into three different subgroups: research universities, comprehensive universities, and focused universities.³ The only public universities not included here are Universiti Malaysia Kelantan, Universiti

Pertahanan Nasional Malaysia, and Universiti Sultan Zainal Abidin, as their data were unavailable. The 17 universities are divided into three groups: 1) five research universities⁴; 2) four comprehensive universities⁵; and 3) eight focused universities.⁶ The data were extracted from the Higher Education Statistical Yearbooks of the Malaysian Ministry of Higher Education (2009) and the Elsevier Scopus database.

As the Hicks–Moorsteen approach is a distance-based index, non-parametric DEA models are employed to estimate the institutions' efficiency and productivity changes. An important advantage of the DEA approach is that it works well with a small sample size. The small sample of 17 universities in this paper is not sufficient for parametric (econometric) techniques. Several studies in the literature also work with small sample sizes (e.g., Tomkins and Green 1988; Sinuany-Stern et al. 1994; Haksever and Muragishi 1998; Korhonen et al. 2001; Emrouznejad and Thanassoulis 2005).

The important issue in the use of the DEA approach relates to the correct selection of inputs and outputs. However, there is no consensus in the literature as to how to specify the inputs and outputs (Avkiran 2001). According to Lindsay (1982, p. 176), some characteristics of the higher education institutions such as “lack of profit motivation, goal diversity and uncertainty, diffuse decision making and poorly understood production technology” differentiate this sector from other industries and complicate the specification of the variables. Carrington et al. (2005) also state that it is difficult to accurately define the university inputs and outputs, because they are diverse and multifaceted.

The choice of inputs and outputs in this study is based on the production approach studies by Athanassapoulos and Shale (1997) and Glass et al. (2006), and Worthington and Lee (2008). These studies assume that universities combine labour and non-labour factors of

production to produce outputs in the form of teaching, research and other educational services.

The four inputs included in our analysis, which are fully described in Table 1 and 2, are as follows: 1) undergraduate enrolments; 2) postgraduate enrolments; 3) the number of full-time equivalent academic staff members; and 4) the allocated government research funding. The student enrolments for undergraduate and postgraduate degrees are important input variables. Both changed significantly after 2006 in most of the universities, with undergraduate enrolment increasing from 223,606 in 2006 to 267,200 in 2009, and postgraduate enrolment increasing from 39,099 in 2006 to 59,137 in 2009. We included total student enrolments, instead of the more commonly used full-time equivalent student loads, due to the unavailability of some data. This difficulty was also experienced by Agasisti and Johnes (2009). Our three outputs are defined as follows: 1) the number of undergraduate qualifications awarded; 2) the number of postgraduate qualifications awarded; and 3) the number of refereed articles as a proxy for research output.

Three observations are noteworthy at this point. First, student inputs are assumed to be homogeneous, because there was no easy way to capture quality. This is consistent with DEA models of previous studies (e.g., Athanassapoulos and Shale 1997; Johnes 2008; Worthington and Lee 2008). Second, some studies have taken into account the quality of undergraduate output by using the number of graduates receiving a first class degree (see Flegg et al. 2004). However, our study has not adopted this approach because of data inaccuracy. Third, we mainly focus on teaching and research as the most important activities of universities. In other words, we have not incorporated a third type of output, community services, because there is no accepted or easy way to evaluate community and consultation services across

universities (see Ahn, et al. 1989; Carrington et al. 2005; Johnes 2008; Worthington and Lee 2008).

[Tables 1 and 2 about here]

There are many ways of measuring university research outputs (e.g., Carrington et al. 2005; Glass et al. 2006). Abbott and Doucouliagos (2003) argue that one should consider both quantity and quality of research outputs. As a proxy for research output, several studies have used research income (e.g., Abbott and Doucouliagos 2003; Flegg et al. 2004; Johnes 2008; Worthington and Lee 2008). Malaysian universities do not usually provide consistent reports of their research outputs; different definitions are used and they frequently change over time. Against this backdrop, we employed an alternative proxy for research output data, known as the pure bibliometric approach, using the number of published research papers in refereed journals.

The bibliometric approach possesses a considerable advantage over other alternatives such as the peer-review approach.⁷ For instance, it costs less, is non-invasive, easy to implement and ensures rapid updates. Application of the bibliometric approach is usually based on data extracted from the Thomson Reuters Web of Science (WoS), a practice common to previous studies (see Abramo and D'Angelo 2011; Abramo et al. 2011). However, the Scopus database is likely a better choice because it covers more refereed journals and conference proceedings than WoS (Meho and Rogers 2008), and also provides the best coverage in social-science literature (Norris and Openheim 2007). It is noteworthy that the WoS database mainly covers the North American, Western European and English-language outlets (Meho and Yang 2007). Thus, in the case of the Malaysian higher education institutions, we consider the Scopus database the most appropriate source.

In the process of counting the number of refereed articles by each university, we took care to ensure the accuracy of the data. For example, issues of affiliation were treated cautiously when some authors used their faculty as their affiliation rather than their university. Additionally, where co-authors were from the same institution, we gave due consideration to the issue of double counting. To overcome this problem, we gave weights to each university based on the total number of authors. For instance, for an article with three authors (two from university A and one from university B), university A was weighted $2/3$ and university B was weighted $1/3$. If we had have given equal weights to all three universities, the results would have been overestimated.

5 Empirical results

Table 3 presents the estimated means of output-oriented technical efficiency (*OTE*), output-oriented scale efficiency (*OSE*), and output-oriented mix efficiency (*OME*) in four different groups of the universities (i.e., research universities, comprehensive universities, focused universities, and the sector as a whole) for the period 2006–2009. Columns 3 to 5 of Table 3 list the means of *OTE*, *OSE* and *OME* for each year, respectively. This table reveals that the technical efficiency and mix efficiency for the sector as a whole decreased between 2006 and 2007 and then rose notably after 2007. More specifically, *OTE* increased from 0.9561 in 2007 to 0.9993 in 2008, and *OME* improved largely from 0.8755 in 2007 to 0.9709 in 2008. Although the mean values for *OTE* and *OME* fell in 2009, the value of these measurements were still higher than those observed prior to 2008, suggesting an overall improvement in the sector after the implementation of policy reforms embedded in the 2007 NHESP. We may argue that the positive changes occurring after 2007 were mainly related to the implementation of the NHESP, which helped the public universities to enhance their staff and resource usage efficiency.

[Table 3 about here]

In terms of scale efficiency, the results are quite mixed. For instance, the focused universities subgroup show low levels of scale efficiency in 2006 and 2008 and high scale efficiency levels in 2007 and 2009. This may be due to the fact that most of these universities had been upgraded from colleges to universities, and were not operating on an optimal scale. However, public universities do not necessarily need to be scale efficient. For example, one possible reason could be that these universities have to follow government prescribed policies, such as opening additional branches in rural areas, as well as encouraging employment of additional staff in such areas.

Table 4 presents the universities' total factor productivity changes (ΔTFP) and its components, technical change ($\Delta Tech$) and efficiency change (ΔEff), for all of the four groups between 2006 and 2009. The table also presents various components of the ΔEff : changes in pure technical efficiency (ΔOTE), residual scale efficiency ($\Delta ROSE$), and mix efficiency (ΔOME). The interpretation of the results is straightforward. An estimated value greater (less) than unity indicates an improvement (worsening) in the corresponding measure.

[Table 4 about here]

A cursory look at Table 4 shows that mix efficiency change (ΔOME) is the major component of the changes in efficiency (ΔEff) in all periods. For instance, in 2006–2007, the sector experienced a significant deterioration in ΔEff by -56.83% ($\Delta Eff = 0.4317$), which was attributable to the 59.4% negative change of ΔOME ($\Delta OME = 0.406$). However, the sector's efficiency change improved markedly by 302.31% ($\Delta Eff = 4.0231$) in 2007–2008 and 45% ($\Delta Eff = 1.452$) in 2008–2009 because of large mix-efficiency developments of 1.9695% ($\Delta OME = 2.9695$) and 0.5323% ($\Delta OME = 1.5323$), respectively. This reflects an overall

improvement in the way the universities' resources were allocated in the post-NHESP era. Table 4 shows that ΔOME is also the most important component of the TFP changes in 2007–2008 and 2008–2009. As a result of large mix efficiency changes in these periods, the sector experienced TFP growth of 28.3% and 62.15% in 2007–2008 and 2008–2009, respectively.

$\Delta Tech$ (technical changes) was found to be the second most important component of TFP changes. Table 4 reveals that $\Delta Tech$ appears to be the same for each university in all periods, suggesting that all institutions have the same access to the same production possibility set.⁸ As a result, any shifts in the production possibility set resulting from changes in external factors and/or government intervention can affect all universities equally, either in terms of improvement or worsening of the production frontier. Table 4 shows that the sector experienced remarkable growth of $\Delta Tech$ in 2006–2007 ($\Delta Tech = 3.2118$) and 2008–2009 ($\Delta Tech = 1.1167$) and a slight negative change in $\Delta Tech$ during 2007–2008 ($\Delta Tech = 0.3188$). Hence, we may conclude that the sector's $\Delta Tech$ largely improved during 2006–2009. One possible explanation for this positive achievement can be related to the widespread use of information technology and electronic learning initiatives launched within the Malaysian universities in this period. As highlighted by Johnes (2008), an increased use of technology and e-learning activities can facilitate the accessibility of information for students, and diversify teaching methods and boost administrative efficiency. In addition, Johnes (2008) states that the technological improvements can also strengthen the universities' research capability to undertake further collaborative research.

A general comparison of TFP changes of different subgroups in Table 4 reveals that research and comprehensive universities that were experiencing productivity regress before 2007 show considerable productivity growth after the implementation of the NHESP. Table 4

also reveals that the focused universities recorded better performance than the other two subgroups in all of the periods. In sum, our results provide convincing evidence that the sector as a whole enjoyed significant productivity progress during the sample period (2006–2009), particularly over the post-NHESP era (2008–2009).

6 Conclusions

This paper uniquely uses an alternative approach to decompose the Hicks–Moorsteen TFP index to examine efficiency and productivity changes in a higher education context. We investigate the efficiency and productivity changes in three groups of the Malaysian public universities (namely, research universities, comprehensive universities, and focused universities) over the period 2006–2009. The study period covers the implementation of the NHESP in 2007 so that a meaningful analysis of productivity and efficiency changes would be feasible. Four different components of productivity changes are estimated: technical changes, changes in pure efficiency, changes in scale efficiency, as well as changes in mix efficiency. Different efficiency measures are also computed.

Based on our findings, the overall sector's mix and technical efficiency levels (output-oriented technical efficiency) decreased in the period 2006–2007, then significantly improved over 2007–2008 and slightly declined during 2008–2009. The overall efficiency improvement of the sector coincided with the implementation of new policies embedded in the NHESP. This plan was aimed at strengthening the principles of good governance in the university delivery system, improving accessibility and equity of resources in the public higher education sector, enhancing the universities' innovation capabilities and the quality of teaching and learning. Thus, we may state that the NHESP has positively affected the efficiency and productivity of various groups of Malaysian universities. As to the slight deterioration of technical efficiency and mix efficiency in 2009, the plan is still progressing,

and public universities have not completely adapted the proposed structure and support mechanisms. Therefore, some of the positive outcomes of the plan cannot be measured until more data become available in the foreseeable future.

We found the observed TFP improvements were mainly attributable to mix efficiency and technological changes. We consider that such achievements are a result of advancements in information, communication, and technology, as well as the increased use of e-learning facilities in the public higher education sector. This result aligns with previous international higher education productivity studies, which found that technological changes were a significant factor in university productivity growth (see Flegg et al. 2004; Johnes 2008; Worthington and Lee 2008).

We also found that the two groups of universities experiencing productivity regresses before 2007 (i.e., research and comprehensive universities) experienced considerable productivity gains after the introduction of the NHESP. Focused universities had the highest level of productivity growth compared to the other two subgroups in all the periods.

While this study has provided evidence of improvements in the efficiency and productivity of Malaysian higher education universities after the 2007 NHESP, there is an urgent need to consider strategies for the sustainability of such achievement. The second phase of the plan, named “Malaysia’s Global Reach: A New Dimension”, will run from 2011 to 2015 with the aim of ensuring that the higher education sector continues to be globally competitive by fostering greater collaboration between Malaysian institutes of higher learning, reinforcing networking and internationalizing the curriculum. The new phase should further strengthen and consolidate Malaysian higher education institutions to be more competitive and support

their contributions in the global arena. Future studies may reveal the effects of these additional reforms.

Table 1 Input and output variables

<i>Variables</i>		<i>Definition of variables</i>
Outputs	Undergraduate qualifications awarded (Y1)	The total number of first degree qualifications awarded
	Postgraduate qualifications awarded (Y2)	The total number of postgraduate degree qualifications awarded
	Research output (Y3)	The number of journal articles published in the Scopus database
Inputs	Undergraduate enrolments (X1)	The total number of first degree enrolments
	Postgraduate enrolments (X2)	The total number of postgraduate student enrolments
	Academic staff (X3)	The number of full-time equivalent academic staff members
	Government research funding (X4)	Funding provided by the government to support research activities

Table 2 Descriptive statistics

<i>Year</i>	<i>Des. Statistics</i>	<i>X1</i>	<i>X2</i>	<i>X3</i>	<i>X4</i>	<i>Y1</i>	<i>Y2</i>	<i>Y3</i>
2006	Mean	13,153.3	2,299.9	1,222.3	10,278,531.8	3,246.6	435.5	88.9
	Min	2,413	37	292	100,021	84	1	0.2
	Max	38,061	9,543	4,966	41,572,260	9,403	1,493	349.6
	S.D.	9,640.9	2,801.3	1,154.6	12,736,402.8	2,596.4	481.7	133.9
	Sum	223,606	39,099	20,779	174,735,041	55,193	7,403	2,332
2007	Mean	14,449.5	2,426	1,359.3	18,129,365.7	3,699.5	541.2	107.4
	Min	1,858	1	354	175,480	428	3.0	0.2

Table 3 Estimated mean output-oriented measures of technical, scale and mix efficiencies using the Hicks–Moorsteen method (2006–2009)

<i>Groups</i>	<i>Year</i>	<i>OTE</i>	<i>OSE</i>	<i>OME</i>
Research universities	2006	0.9784	0.9986	0.9784
	2007	1.0000	0.9823	0.9679
	2008	1.0000	0.9766	0.9936
	2009	0.9718	0.9944	0.9412
Comprehensive Universities	2006	0.9496	0.9925	0.9486
	2007	0.9390	0.9836	0.7521
	2008	1.0000	0.9863	0.9222
	2009	0.9558	0.9399	0.8886
Focused universities	2006	1.0000	0.8990	0.8939
	2007	0.9292	0.9889	0.9066
	2008	0.9979	0.8735	0.9971
	2009	1.0000	0.9694	1.0000
The sector	2006	0.9759	0.9634	0.9403
	2007	0.9561	0.9849	0.8755
	2008	0.9993	0.9455	0.9709
	2009	0.9760	0.9679	0.9433

Note: *OTE* = output-oriented technical efficiency; *OSE* = output-oriented scale efficiency; *OME* = output-oriented mix efficiency.

Table 4 TFP changes and its components for different university sub-grouping between 2006 and 2009

<i>Groups</i>	<i>Period</i>	ΔTFP	$\Delta Tech$	ΔEff	ΔOTE	$\Delta ROSE$	ΔOME
Research universities	2006–2007	0.9793	3.2118	0.3049	1.0228	0.9897	0.3012
	2007–2008	1.2026	0.3188	3.7723	1.0000	1.0271	3.6729
	2008–2009	1.7212	1.1167	1.5413	0.9718	0.9476	1.6738
Comprehensive universities	2006–2007	0.9817	3.2118	0.3057	1.0021	0.7784	0.3919
	2007–2008	1.2177	0.3188	3.8198	1.0704	1.3938	2.5603
	2008–2009	1.2050	1.1167	1.0790	0.9558	0.9605	1.1755
Focused universities	2006–2007	2.3048	3.2118	0.7176	0.9292	1.4715	0.5249
	2007–2008	1.3392	0.3188	4.2009	1.1613	1.3522	2.6754
	2008–2009	1.9617	1.1167	1.7567	1.0021	1.0030	1.7478
The sector	2006–2007	1.3865	3.2118	0.4317	0.9847	1.0799	0.4060
	2007–2008	1.2826	0.3188	4.0231	1.0772	1.2577	2.9695
	2008–2009	1.6215	1.1167	1.4520	0.9766	0.9703	1.5323

Note: $\Delta TFP = \Delta Tech \times \Delta Eff$ and $\Delta Eff = \Delta OTE \times \Delta ROSE \times \Delta OME$.

Notes

¹ Gilbert and Wilson (1998), Glass and McKillop (2000) and Arjomandi et al. (2011) experienced this difficulty in their studies of the Korean banks, UK building societies, and Iranian banks, respectively.

² Briec and Kerstens (2004) also proposed an interesting difference-based variation of the Malmquist index known as the Luenberger–Hicks–Moorsteen indicator in the literature. For more recent theoretical contributions on the Hicks–Moorsteen index see also Briec and Kerstens (2011), Briec et al. (2012), and Kerstens and Van de Woestyne (2014).

³ Research universities are well-established, research-intensive institutions. According to Malaysian Ministry of Higher Education (2007), this category is awarded to universities that place emphasis on aspects of research and development. These universities share the following features: (a) research-oriented subject areas; (b) competitive entry requirement; (c) highly-qualified academics. Comprehensive universities (also called multi-disciplinary universities) focus on a wide range of courses and fields of specialization. The four common characteristics among these universities are: (a) wide range of subject areas; (b) competitive entry requirement; (c) highly-qualified academics. Focused universities focus on certain fields of knowledge related to the original objective of their establishment. They have the same characteristics as research universities.

⁴ All research is on the focused and established institutions: Universiti Malaya, Universiti Sains Malaysia, Universiti Kebangsaan Malaysia, Universiti Putra Malaysia, and Universiti Teknologi Malaysia.

⁵ Also called multi-disciplinary universities, which focus on a wide cross-section of courses and fields of study: Universiti Islam Antarabangsa Malaysia, Universiti Malaysia Sarawak, Universiti Malaysia Sabah, and Universiti Teknologi MARA.

⁶ They concentrate on specified disciplines linked to the original objective of their establishment: Universiti Utara Malaysia, Universiti Pendidikan Sultan Idris, Universiti Malaysia Terengganu, Universiti Sains Islam Malaysia, Universiti Tun Hussein Onn, Universiti Teknikal Melaka Malaysia, Universiti Malaysia Pahang, and Universiti Malaysia Perlis.

⁷ Peer-review approach is an evaluation process of research output carried out by qualified individuals within the relevant areas. This approach was adopted by Johnes (1995) and Meng et al. (2008).

⁸ This is entirely consistent with the theory behind technical changes explained by O'Donnell (2012a).
