Unitary differential space-time-frequency codes for MB-OFDM UWB

Abstract
In a multiple-input multiple-output (MIMO) multiband orthogonal frequency division multiplexing (MB-OFDM) ultra-wideband (UWB) system, coherent detection where the channel state information (CSI) is assumed to be exactly known at the receiver requires the transmission of a large number of symbols for channel estimation, thus reducing the bandwidth efficiency. This paper examines the use of unitary differential space-time frequency codes (DSTFCs) in MB-OFDM UWB, which increases the system bandwidth efficiency due to the fact that no CSI is required for differential detection. The proposed DSTFC MB-OFDM system would be useful when the transmission of multiple channel estimation symbols is impractical or uneconomical. Simulation results show that the application of DSTFCs can significantly improve the bit error performance of conventional differential MB-OFDM system (without MIMO).

Abstract—In a multiple-input multiple-output (MIMO) multi-band orthogonal frequency division multiplexing (MB-OFDM) ultra-wideband (UWB) system, coherent detection where the channel state information (CSI) is assumed to be exactly known at the receiver requires the transmission of a large number of symbols for channel estimation, thus reducing the bandwidth efficiency. This paper examines the use of unitary differential space-time frequency codes (DSTFCs) in MB-OFDM UWB, which increases the system bandwidth efficiency due to the fact that no CSI is required for differential detection. The proposed DSTFC MB-OFDM system would be useful when the transmission of multiple channel estimation symbols is impractical or uneconomical. Simulation results show that the application of DSTFCs can significantly improve the bit error performance of conventional differential MB-OFDM system (without MIMO).

Index Terms—UWB, MB-OFDM, DSTFC, STFC, MIMO.

I. INTRODUCTION

Combination of the emerging technologies multi-band orthogonal frequency division multiplexing ultra-wideband (MB-OFDM UWB) [1], multiple-input multiple-output (MIMO), and space-time-frequency codes (STFCs) may provide a significant improvement in the form of maximum achievable communication range, bit error performance, system capacity, data rate, or a combined form of those. The combination of MB-OFDM UWB, MIMO and STFCs to which we will refer as STFC MB-OFDM UWB systems has been considerably examined in the literature, such as [2], [3], [4], [5], [6], [7], [8].

In all aforementioned works, channel state information (CSI) is assumed to be known exactly at the receiver, thus allowing the receiver to perform coherent detection. According to [1], six MB-OFDM symbols are transmitted in the physical layer convergence protocol (PLCP) preamble for channel estimation between each pair of Tx and Rx antennas, thus facilitating coherent detection at the receiver. In a MIMO system consisting of \( M \) Tx and \( N \) Rx antennas, the required number of symbols for this purpose might be as large as \( 6MN \), except for the case where superimposed training techniques, such as in [9], [10], [11], are used to reduce the number of channel estimation symbols transmitted within the preamble. Therefore, transmission of large number of MB-OFDM symbols for channel estimation reduces significantly the system bandwidth efficiency. In fast fading channels or in very high data rate systems, transmission of large number of MB-OFDM symbols for channel estimation is a hassling task and might even be impractical or uneconomical. In these cases, non-coherent detection (or differential detection), where no CSI is required for decoding signals at the receiver, would be the best candidate.

For differential transmission in general OFDM systems associated with a MIMO model, various techniques have been proposed in the literature, such as [12], [13], [14], [15], [16] and [17]. However, differential transmission in MB-OFDM systems associated with MIMO has not been considered yet. There are two main differences between channel characteristics in conventional OFDM systems and in MB-OFDM UWB ones. Firstly, channels in the latter are much more dispersive than those in the former, with the average number of multipaths in some channel models reaching some thousands [18]. Secondly, channel coefficients in the former are usually considered to be Rayleigh distributed, while those in the latter are log-normally distributed [18]. These differences of MBOFDM systems require simulations to be run with the special channel model that has been proposed in [18]. This will be mentioned in detail later in the simulation section of this paper.

Besides the different channel model, a MB-OFDM system differs from a general OFDM one in the fact that the former transmits consecutive MB-OFDM symbols at different frequency sub-bands thanks to the application of different Time-Frequency Codes (TFCs) [1, p.60]. This technique should also be taken into account in the proposal of the differential space-time-frequency codes (DSTFCs) MB-OFDM system. This issue will be discussed later in Section III of this paper.

For the above reasons, the systems incorporating MBOFDM UWB, MIMO and differential transmission must be more specifically analyzed, though there exist several similarities between those systems and the systems incorporating conventional OFDM, MIMO and differential transmission. Thus this paper is the first case study that examines the application of DSTFCs in MB-OFDM UWB communications.

The paper is organized as follows. Section II reviews briefly the mathematical model of our proposed STFC MB-OFDM UWB system [4]. In Section III, unitary DSTFCs are proposed for MB-OFDM UWB and decoding metrics are derived for the proposed DSTFCs. Simulation results are mentioned in Section IV and conclusions are derived in Section V.

Notations: The following notations will be used throughout the paper. The superscripts \( (\cdot)^* \), \( (\cdot)^T \) and \( (\cdot)^H \) denote the
complex conjugation, transposition operation and conjugate transpose operation respectively. We denote \( \bar{a}_j \cdot b_j \), \( \bar{a}_j \otimes b_j \) and \( \bar{a}_j \ast b_j \) to be the element-wise (or Hadamard) product, the linear convolution and the cyclic convolution between the two vectors \( \bar{a}_j \) and \( b_j \) respectively. Denote \( N_{fft} \) to be the FFT/IFFT size (for MB-OFDM UWB communications [1], \( N_{fft} = 128 \)). Further, \( \Re\{c\} \) and \( \Im\{c\} \) denote the real and imaginary parts of the complex number \( c \). The notation \( \text{diag}(\bar{a}_j) \) denotes a square diagonal matrix formed by stacking the vector \( \bar{a}_j \) on the main diagonal of the matrix, while \( \{\text{diag}(\bar{a}_j)\}_{M \times N} \) denotes a \( M \times N \)-sized rectangular matrix whose elements are diagonal matrices \( \text{diag}(\bar{a}_j) \). We state that the two subsets of indices \( \{m, k\} \) and \( \{\bar{m}, \bar{k}\} \) to be different, denoted as \( \{m, k\} \neq \{\bar{m}, \bar{k}\} \), if at least one of the following two inequalities \( m \neq \bar{m} \) and \( k \neq \bar{k} \) occurs. Finally, we define \( 1 \) as a column vector of length \( N_D \), whose elements are all \( 1 \).

II. STFC MB-OFDM UWB SYSTEM

The proposed STFC MB-OFDM UWB system [4] consisting of \( M \) Tx antennas and \( N \) Rx antennas, with the notations of signals at the considered reference points, is depicted in Fig. 1. The transmitted STFC is denoted as a matrix \( \bar{S}_t = [\bar{s}_{t,m}]_{T \times M} \), where \( T \) denotes the number of MB-OFDM symbol time slots required to transmit the whole STFC block. The code matrix \( \bar{S} \) can be structured in a similar way as orthogonal space-time block codes (OSTBCs) [19], [20], [21] or quasi-orthogonal space-time block codes (QOSTBCs) [22] in conventional wireless STBC MIMO systems, except that for each element \( \bar{s}_{t,m} \) is not a complex number, but is defined as a column vector \( \bar{s}_{t,m} = [s_{t,m,1}, s_{t,m,2}, \ldots, s_{t,m,N_{fft}}]^T \). The vectors \( \bar{s}_{t,m} \) are the original transmitted data before IFFT. The symbols \( s_{t,m,k} \) for \( k = 1, \ldots, N_{fft} \), are drawn from a PSK, QAM or dual carrier modulation (DCM) [23] signal constellation.

Denote \( \chi = [\bar{x}_{\text{OFDM},t,m}]_{T \times M} \) to be the matrix whose elements are the \( N_{fft} \)-point IFFTs of the respective elements in \( \bar{S}_t \), then \( \chi = \{\text{IFFT}(\bar{s}_{t,m})\}_{T \times M} = [\bar{x}_{\text{OFDM},t,m}]_{T \times M} \). The symbols \( \bar{x}_{\text{OFDM},t,m} \) are referred to as MB-OFDM symbols. Further, denote \( \lambda_{ZPS} = [\bar{x}_{ZPS,t,m}]_{T \times M} \) to be the matrix whose elements are the respective elements in \( \chi \) appended by a zero padded suffix (ZPS), which, according to [1], includes 37 zeros. At the transmission of the \( t \)-th MB-OFDM symbol, we denote \( \bar{h}_{t,m,n} = [h_{t,m,n,1}, h_{t,m,n,2}, \ldots, h_{t,m,n,L_{max}}]^T \) to be the channel vector between the \( m \)-th Tx and \( n \)-th Rx antennas, for \( m = 1, \ldots, M, n = 1, \ldots, N \), where the channel coefficients \( h_{m,n,l} \) of the \( t \)-th path, \( l = 1, \ldots, L_{max} \), in this channel are modeled as independent log-normally distributed random variables (RVs). Let \( L_{max} = \max\{L_{m,n}\} \), for \( m = 1, \ldots, M, n = 1, \ldots, N \). Denote the MB-OFDM UWB channel coefficient matrix as \( \bar{H} = \{\bar{b}_{m,n,ZPS}\}_{M \times N} \) where the vector \( \bar{h}_{m,n,ZPS} \) is created from the corresponding channel vector \( \bar{h}_{m,n} \) by adding zeros to have the length \( L_{max} \).

At the transmission of the \( t \)-th MB-OFDM symbol, the received signal at the \( n \)-th Rx antenna is calculated as

\[
\bar{r}_{ZP,t,n} = \sum_{m=1}^{M} (\bar{S}_{ZP,t,m} \odot \bar{h}_{t,m,n}) + \bar{n}_{t,n}.
\]

The elements of noise vector \( \bar{n}_{t,n} \) are considered to be independent complex Gaussian RVs.

In MB-OFDM system, a ZPS of length \( N_{ZPS} = 37 \) is appended to each symbol \( \bar{x}_{\text{OFDM},t,m} \) at the transmitter to create a transmitted symbol \( \bar{x}_{ZPS,t,m} \). At the receiver, an overlap-and-add operation (OAAO) must be performed before FFT (i.e. \( N_{ZPS} \) samples of a received symbol \( \bar{r}_{ZP,t,n} \) from \( (N_{fft}+1) \) to \( N_{fft}+N_{ZPS} \) are added to the beginning of that received symbol. Then the first \( N_{fft} \) samples of the resulting symbol will be used to decode the transmitted symbol). As a result, after performing OAAO for the received signal \( \bar{r}_{ZP,t,n} \) in (1) and then taking the first \( N_{fft} \) resulting samples, denoted as \( \bar{r}_{\text{OFDM},t,n} \), the following equation is deduced

\[
\bar{r}_{\text{OFDM},t,n} = \sum_{m=1}^{M} \bar{s}_{\text{OFDM},t,m} \ast \bar{h}_{t,m,n} + \bar{n}_{t,n}.
\]

For the circular convolution, we have the following property

\[
\bar{x}_{\text{OFDM},t,m} \ast \bar{h}_{t,m,n} = \text{IFFT}\{\text{FFT}\{\bar{x}_{\text{OFDM},t,m}\} \odot \text{FFT}\{\bar{h}_{t,m,n}\}\}
= \text{IFFT}\{\bar{s}_{t,m} \ast \bar{h}_{t,m,n}\}
\]

where \( \bar{h}_{t,m,n} \) is the \( N_{fft} \)-point FFT of the channel vector \( \bar{h}_{t,m,n} \), i.e. \( \bar{h}_{t,m,n} = \text{FFT}\{\bar{h}_{t,m,n}\} \). We denote \( \bar{h}_{t,m,n} = [h_{t,m,n,1}, h_{t,m,n,2}, \ldots, h_{t,m,n,L_{max}}]^T \).

After going through the FFT block at the receiver, the received signal becomes

\[
\text{FFT}\{\bar{x}_{\text{OFDM},t,n}\} = \sum_{m=1}^{M} \bar{s}_{t,m} \ast \bar{h}_{t,m,n} + \text{FFT}\{\bar{n}_{t,n}\}.
\]

Denote \( \bar{\tau}_{t,n} = [\bar{r}_{t,n,1}, \bar{r}_{t,n,2}, \ldots, \bar{r}_{t,n,N_{fft}}]^T \) and \( \bar{n}_{t,n} = [\bar{n}_{t,n,1}, \bar{n}_{t,n,2}, \ldots, \bar{n}_{t,n,N_{fft}}]^T \) as the FFT\{\bar{x}_{\text{OFDM},t,n}\} and FFT\{\bar{n}_{t,n}\}. Then (2) can be rewritten as follows

\[
\bar{\tau}_{t,n} = \sum_{m=1}^{M} \bar{s}_{t,m} \ast \bar{h}_{t,m,n} + \bar{n}_{t,n}.
\]

Recall that \( \bar{s}_{t,m} \) is the original modulated signal (before IFFT).
Denote $\mathcal{H}_t = \{h_{t,m,n}\}_{M \times N}$ to be the matrix whose elements are the $N_{fft}$-point FFTs of the respective elements in the channel coefficient matrix $\mathbf{H}$. Further, denote $\mathbf{R}_t = \{\mathbf{r}_{t,n}\}_{T \times N}$ to be the received signal matrix, $\mathcal{R}_t = \{\bar{r}_{t,n}\}_{T \times N}$ to be the received signal matrix after FFT, and $\mathcal{N} = \{n_{t,n}\}_{T \times N}$ to be the noise matrix. We can rewrite (3) in matrix form as follows

$$\mathcal{R}_t = \mathbf{S}_t \circ \mathcal{H}_t + \mathcal{N}_t \quad (4)$$

where we define the multiplication operation $\circ$ between $\mathbf{S}$ and $\mathcal{H}_t$ such that the $(t,n)$-th element of the resulting matrix is a $N_{fft} \times 1$-sized column vector $\sum_{m=1}^{M} \bar{s}_{t,m} \cdot \bar{h}_{t,m,n}$.

If we rewrite $\mathcal{R}_t$, $\mathbf{S}_t$, $\mathcal{H}_t$ and $\mathcal{N}_t$ in (4) in the following form

$$\mathcal{R}_t = \{\text{diag}(\bar{r}_{t,n})\}_{T N_{fft} \times N N_{fft}},$$
$$\mathcal{H}_t = \{\text{diag}(\bar{h}_{t,m,n})\}_{M N_{fft} \times N N_{fft}},$$
$$\mathbf{S}_t = \{\text{diag}(\bar{s}_{t,m})\}_{T N_{fft} \times N N_{fft}},$$
$$\mathcal{N}_t = \{\text{diag}(\bar{n}_{t,n})\}_{T N_{fft} \times N N_{fft}},$$

then (4) can be rewritten with the normal definition of matrix multiplication as follows

$$\mathcal{R}_t = \mathbf{S}_t \mathcal{H}_t + \mathcal{N}_t \quad (5)$$

Channel coefficients are assumed to be known at the receiver to facilitate the coherent detection. In this case, due to the full orthogonality of STFCs [4], each MB-OFDM symbol $\bar{s}_{t,m}$, which is a $(N_{fft} \times 1)$-sized column vector, can be decoded separately. The decoding process is even more simplified by the fact that each element $s_{t,m,j}$ within $\bar{s}_{t,m}$ can also be decoded separately. In the case of QOSTFCs, thanks to the partial orthogonality of QOSTFCs [7], [8], each pair of MB-OFDM symbols each of which is a $(N_{fft} \times 1)$-sized column vector can be decoded separately. Similarly, the decoding process is even more simplified by the fact that each pair of elements that are parts of the MB-OFDM symbols of the same MB-OFDM symbol can also be decoded separately. We refer readers to the publications [4], [7], [8] for more detail about the decoding metrics of STFCs and QOSTFCs in coherent detection.

III. DIFFERENTIAL STFCs IN MB-OFDM UWB

The proposed model of a DSTFC MB-OFDM UWB system requiring no transmission of channel estimation symbols is depicted in Fig. 2. As opposed to the STFC MB-OFDM system mentioned above where channels are normally assumed to be constant during multiple blocks of the transmitted STFC, in the DSTFC MB-OFDM system, it is required that channels must be constant during at least two consecutive blocks of the transmitted DSTFC. Thus the DSTFC MB-OFDM system is better fit for fast fading channels. Let us assume generally that channels in the DSTFC MB-OFDM system are constant during a time window $T_{SYM}$ (ns) where $K$ is an integer

$\bar{\mathbf{w}}_t = \left[ \begin{array}{c} \bar{w}_{t,1} \\ \bar{w}_{t,2} \\ -\bar{w}_{t,2} \\ \bar{w}_{t,1} \end{array} \right]$, \quad (10)

As stated earlier in Section I, in a MB-OFDM system, consecutive MB-OFDM symbols are transmitted over different sub-bands. Thus, in the proposed DSTFC MB-OFDM system, the MB-OFDM symbols (the column vectors) in the same row of the matrix $\mathbf{W}_t$, which will be transmitted over different Tx antennas in the same MB-OFDM symbol time slot, must be transmitted over the same sub-band. The MB-OFDM symbols

Fig. 2. Structural diagram of the proposed DSTFC MB-OFDM UWB system.
in the same column of the matrix $W_t$, which will be transmitted over a certain Tx antenna during different MB-OFDM symbol time slots, can be instead transmitted over different sub-bands, according to different TFCs [1, p.60].

The assumption of channels being constant within a time window $2K T_{SYM}$ is equivalent to the fact that channels are constant during the transmission of $K$ consecutive Alamouti code blocks. Therefore, the encoding principle (9) should be applied for $t = 1, \ldots, (K - 1)$ and the whole transmission protocol is reset for a new time window. Since $S_t$ is a unitary matrix, every transmitted code word $W_t$ is also a unitary one, i.e. $W_t^H W_t = I_{2N_f,t}$. The transmission model can be expressed as follows
\[
R_t = W_t H_t + N_t. \tag{11}
\]

We will now derive the maximum likelihood (ML) decoding metric for the proposed DSTFC. To do that, we first represent the STFC in (7) in the following form
\[
S_t = 1/\sqrt{2} \sum_{m=1}^{N_f,t} \left( s^{R}_{t,m,k} s_{t,m,k}^I + i Y_{t,m,k} s_{t,m,k}^I \right),
\]
where $s_{t,m,k}^R$ and $s_{t,m,k}^I$ are the real and imaginary parts of the symbol $s_{t,m,k}$ respectively, i.e. $s_{t,m,k} = s_{t,m,k}^R + i s_{t,m,k}^I$, while $H_{t,m,k}$ and $Y_{t,m,k}$ are their corresponding weighting matrices. We recall that the symbols $s_{t,m,k}$ are drawn from the original PSK or 4QAM signal constellation.

The weighting matrices $H_{t,m,k}$ and $Y_{t,m,k}$ in the matrix (7) always satisfy the properties for a given value $t$
\[
\begin{align*}
X_{t,m,k} \bar{X}_{t,m,k}^H &= I, \quad Y_{t,m,k} \bar{Y}_{t,m,k}^H = I, \quad \forall m, k, \tag{12} \\
X_{t,m,k} \bar{X}_{t,n,k}^H &= -X_{t,m,k} \bar{X}_{t,n,k}^H, \quad \forall m \neq n, k, \tag{13} \\
Y_{t,m,k} \bar{Y}_{t,n,k}^H &= -Y_{t,m,k} \bar{Y}_{t,n,k}^H, \quad \forall m \neq n, k, \tag{14} \\
X_{t,m,k} \bar{Y}_{t,n,k}^H &= Y_{t,n,k} \bar{X}_{t,m,k}, \quad \forall m, n, k. \tag{15}
\end{align*}
\]

To formulate the ML decoding metric for the symbol $s_{t,m,k}$, for $t = 1, \ldots, (K - 1)$, $m = 1, 2$ and $k = 1, \ldots, N_{f,t}$, let us consider the following term
\[
D_{m,k} = D_{m,k}^R + i D_{m,k}^I,
\]
where
\[
D_{m,k}^R = \Re\{tr(\bar{W}_t^H \bar{R}_{t-1} X_{t,m,k})\},
\]
\[
D_{m,k}^I = \Re\{tr(\bar{W}_t^H \bar{I}_{t-1} Y_{t,m,k})\}.
\]

We have
\[
D_{m,k}^R = \Re\{tr(\bar{W}_t^H \bar{R}_{t-1} X_{t,m,k})\}
= \Re\{tr([\bar{H}_t^H \bar{H}_t - \mathbb{I}_t^H](\bar{W}_t^H \bar{N}_t - \mathbb{I}_t^H)) X_{t,m,k})\}
= \Re\{tr([\bar{H}_t^H \bar{H}_t - \mathbb{I}_t^H](\bar{W}_t^H \bar{N}_t - \mathbb{I}_t^H)) X_{t,m,k})\},
\]
where
\[
\mathbb{N} := \mathbb{H}_t^H \mathbb{W}_t^H \mathbb{N}_{t-1}^H + \mathbb{N}_t^H \mathbb{W}_t^H \mathbb{N}_{t-1} + \mathbb{N}_t^H \mathbb{N}_{t-1}.
\]

Because $\mathbb{W}_{t-1}$ is a unitary matrix, i.e.
\[
\mathbb{W}_{t-1}^H \mathbb{W}_{t-1} = I_{2N_f,t},
\]
and channel coefficients are constant during a time window of $K$ code blocks, i.e. $\mathbb{H}_t = \mathbb{H}_{t-1}$, Eq. (16) becomes
\[
D_{m,k}^R = \Re\{tr([\mathbb{H}_t^H \mathbb{H}_t] (\mathbb{H}_t^H X_{t,m,k}))\} + \Re\{tr(\mathbb{N}_t X_{t,m,k})\}.
\]

The first term is calculated as follows
\[
\Re\{tr(\mathbb{H}_t^H \mathbb{H}_t X_{t,m,k})\} = \frac{1}{\sqrt{2}} \Re\{tr(\mathbb{H}_t^H \mathbb{H}_t X_{t,m,k} X_{t,m,k}^R)\}
= \sum_{\forall \tilde{m}, \tilde{k}, \{\tilde{m}, \tilde{k}\} \neq \{m, k\}} \Re\{tr(\mathbb{H}_t^H \mathbb{H}_t X_{t,m,k} X_{t,m,k}^R)\}
+ \Re\{tr(\mathbb{N}_t X_{t,m,k} X_{t,m,k}^R)\}.
\]

It is noted that if $\Phi$ is an antihermitean (or skew-Hermitian) matrix, i.e. $\Phi^H = -\Phi$, then $tr(\Phi \mathbb{A} \Phi^H)$ is imaginary, thus $\Re\{tr(\Phi \mathbb{A} \Phi^H)\} = 0$. From (13), (16) is easy to check that $\Re\{tr(\mathbb{H}_t^H \mathbb{H}_t X_{t,m,k} X_{t,m,k}^R)\} = 0$.

The symbols $s_{t,m,k}$ are drawn from the original PSK or 4QAM signal constellation.

On the other hand, if $\Theta$ is a Hermitian matrix, i.e. $\Theta^H = \Theta$, then $tr(\Theta \mathbb{A} \Theta^H)$ is real, thus $\Re\{tr(\Theta \mathbb{A} \Theta^H)\} = 0$. From (15), it is trivial to realize that $\Re\{tr(\mathbb{H}_t^H \mathbb{H}_t X_{t,m,k} X_{t,m,k}^R)\} = 0$.

To formulate the ML decoding metric for the symbol $s_{t,m,k}$, for $t = 1, \ldots, (K - 1)$, $m = 1, 2$ and $k = 1, \ldots, N_{f,t}$, let us consider the following term
\[
D_{m,k} = D_{m,k}^R + i D_{m,k}^I,
\]
where
\[
D_{m,k}^R = \Re\{tr(\bar{W}_t^H \bar{R}_{t-1} X_{t,m,k})\},
\]
\[
D_{m,k}^I = \Re\{tr(\bar{W}_t^H \bar{I}_{t-1} Y_{t,m,k})\}.
\]

We have
\[
D_{m,k}^R = \Re\{tr(\bar{W}_t^H \bar{R}_{t-1} X_{t,m,k})\}
= \Re\{tr([\bar{H}_t^H \bar{H}_t - \mathbb{I}_t^H](\bar{W}_t^H \bar{N}_t - \mathbb{I}_t^H)) X_{t,m,k})\}
= \Re\{tr([\bar{H}_t^H \bar{H}_t - \mathbb{I}_t^H](\bar{W}_t^H \bar{N}_t - \mathbb{I}_t^H)) X_{t,m,k})\},
\]
where
\[
\mathbb{N} := \mathbb{H}_t^H \mathbb{W}_t^H \mathbb{N}_{t-1} - \mathbb{I}_t^H \mathbb{W}_t^H \mathbb{N}_{t-1} + \mathbb{N}_t^H \mathbb{N}_{t-1}.
\]
The ML decoding metric for $s_{t,m,k}$ can be derived as follows

$$
\hat{s}_{t,m,k} = \arg\min_{s_{t,m,k} \in \mathbb{C}} |D_{m,k} - \frac{1}{\sqrt{2}} \text{tr}(C_{t,m,k}) s_{t,m,k}|^2
$$

$$
= \arg\min_{s_{t,m,k} \in \mathbb{C}} \left( |D_{m,k}|^2 + \frac{1}{2} |\text{tr}(C_{t,m,k})|^2 |s_{t,m,k}|^2 - \sqrt{2} \text{tr}(C_{t,m,k}) \Re\{D^*_{m,k} s_{t,m,k}\} \right)
$$

$$
= \arg\max_{s_{t,m,k} \in \mathbb{C}} \left( \Re\{D^*_{m,k} s_{t,m,k}\} \right),
$$

Equation (21) means that each of the two MB-OFDM symbols $s_{t,m,k}$ can be separately decoded. Furthermore, each symbol $s_{t,m,k}$ within these two MB-OFDM symbols can also be separately decoded based on the above equation. In other words, instead of jointly decoding all $2N_{fft}$ symbols $s_{t,m,k}$ within the two MB-OFDM symbols $\bar{s}_{t,1}$ and $\bar{s}_{t,2}$ at a time, each of them can be separately decoded. No CSI is required for the decoding process. All we need for the decoding process at time $t$ are the received signals at the previous time $(t-1)$ and at the current time. The decoding process is completely linear, thus relatively simple.

### IV. Simulation Results

To examine the performance advantage of the proposed DSTFC MB-OFDM system, several Monte-Carlo simulations were run in Matlab\textsuperscript{TM} for the baseband, conventional differential MB-OFDM system (without MIMO) and the baseband Alamouti DSTFC MB-OFDM system at the bit rate 320 Mbps. The conventional differential MB-OFDM system was simply created in a similar way as Eq. (9), but it was much more simplified because transmission was carried out in a symbol-by-symbol basis rather than a block-by-block basis in a DSTFC MB-OFDM system. In particular, the transmitted MB-OFDM symbol at time $t$ is the Hadamard product of the transmitted symbol at time $t-1$ and an information symbol. The initial transmitted symbol is set to the vector $\mathbf{1}$. Decoding process was also carried out in a similar manner to Eq. (21).

Each run of simulations was carried out with 1200 Alamouti DSTFC blocks. One hundred channel realizations of each channel model (CM 1 to CM 4) were considered for the transmission of each DSTFC block. The channel realizations were created by the Matlab program enclosed in the appendix of the IEEE 802.15.3a channel modeling sub-committee report [18]. Channel coefficients were assumed to be constant during every two consecutive transmissions of DSTFC blocks. In simulations, $SNR$ is defined to be the signal-to-noise ratio (dB) per sample in a MB-OFDM symbol (consisting of 165 samples), at each Rx antenna (i.e. the subtraction between the total power (dB) of the received signal corresponding to the sample of interest and the power of noise (dB) at that Rx antenna). In both systems, symbols $s_{t,m,k}$ were drawn from unitary QPSK signal constellations, i.e. $|s_{t,m,k}|^2 = 1$. This condition, along with the unitary structure of the transmitted DSTFC blocks, guarantees the power constraint, i.e. the total powers transmitted from all Tx antennas are equal in both systems at any time, in order to fairly compare their performance. The complete set of simulation parameters is presented in Table I.

Fig. 3 compares the bit error performance of the two systems in the case where the receiver is equipped with only one Rx antenna. From this figure, the proposed DSTFC system brings about a significant improvement in the bit error performance, compared to the conventional differential MB-OFDM system. For instance, the Alamouti DSTFC provides approximately a 4 dB gain in the case of CM 1 at the bit error rate $BER = 10^{-3}$. The more dispersive the channel is (CM 1 is the least dispersive channel model while CM 4 is the most dispersive one), the higher gain the DSTFC provides.

Fig. 4 presents the bit error performance of the two systems in the case of two Rx antennas. Once again, we can see that DSTFCs improve significantly the bit error performance of MB-OFDM systems. For illustration, a gain of at least 6 dB (over the conventional differential MB-OFDM system) can be achieved at $BER = 10^{-5}$ when the Alamouti DSTFC is utilized. It is noted that the aforementioned improvements were gained without any increase of total transmission power.

### V. Conclusions

The paper has proposed the framework of DSTFC MB-OFDM UWB systems using the unitary Alamouti DSTFC. It has been shown that MIMO MB-OFDM systems using DSTFCs can possess much better bit error performance, compared to the conventional differential MB-OFDM UWB without MIMO. Furthermore, beside the case study of DSTFC MB-OFDM UWB, it is our conjecture that the proposed DSTFC
principle might be applied in various other wireless applications, such as WiMax MIMO [24], providing better BER than the respective WiMax without MIMO. Examination of the application of DSTFCs in WiMax MIMO will be our future work.
