A profile of patients receiving palliative care in South Australia for July - December 2018

Abstract
The Palliative Care Outcomes Collaboration (PCOC) is a national program that aims to improve the quality and outcomes of palliative care in Australia. This is achieved via a standardised clinical language that supports a national data collection. This report provides a high level profile of 1,903 patients who received palliative care in South Australia during July to December 2018 and had their pain, symptom, family / carer and psychological / spiritual issues assessed as part of routine clinical care.

Keywords

The average age for females was 71.4 years
Diagnosis

Diagnosis reflects the primary illness responsible for the person requiring palliative care. These illnesses are classified as either malignant (cancer) or non-malignant (illnesses other than cancer). Figure 2 shows how the split between malignant and non-malignant has changed since 2016, whilst Figure 3 shows a more detailed breakdown of diagnoses for the current six-months.

Figure 2  Diagnosis over time

Figure 3  Diagnosis

Lung and colorectal cancer are the most common illnesses, accounting for 28.2% of all palliative care patients.

Respiratory failure and cardiovascular disease are the most common non-malignant diagnoses, accounting for 6.6% of all patients.

Note: Only includes episodes that started during each six month reporting period.

Figure 4  Phase as beginning of episode

The most common first phase is **deteriorating** with an average duration of 11.5 days.

Figure 5  First phase of episode over time
Despite pain often being thought to be the most distressing symptom at the end of life, the patient rated symptom with the highest number of severe scores is fatigue (7.7%). The symptom causing the least distress is nausea, rated by patients as ‘absent’ 74.9% of the time.
Palliative care phase

The palliative care phase type describes the stage of the patient’s illness and provides a clinical indication of the level of care a patient requires. Table 3 describes the number of phases and phase length.

<table>
<thead>
<tr>
<th>Phase type</th>

</tr>
<tr>
<td><strong>All phases</strong></td>
<td><strong>5,062</strong></td>
<td><strong>100.0</strong></td>
<td><strong>12.1</strong></td>
</tr>
</tbody>
</table>

Note: Phase records where phase length was greater than 90 days were considered to be atypical and are excluded from the average calculations.

The **deteriorating phase** is the most common with an average duration of 13.4 days.

Place of death

For July - December 2018, 1,321 patients died in the care of a specialist palliative care service. Of these deaths, 24.3% occurred at the persons home, 11% in a residential aged care facility and 63.8% in hospital.

Glossary

AKPS  The Australia-modified Karnofsky Performance Status (AKPS) is a measure of the patient’s performance across the dimensions of activity, work and self-care at phase start. It is a single score between 10 and 100 assigned by a clinician based on observations of a patient’s ability to perform common tasks relating to activity, work and self-care.

Episode  An episode of care is a period of contact between a patient and a palliative care service that is provided by one palliative care service and occurs in one setting. An episode of care ends when either; the patient is formally separated from the current setting of care; the patient dies; or the principal clinical intent of the care changes and the patient is no longer receiving palliative care. Under this definition, a patient receiving palliative care is likely to have more than one episode of care.

Patient  PCOC defines a patient as a person for whom a palliative care service accepts responsibility for assessment and/or treatment as evidenced by the existence of a medical record. Family / carers are included in this definition if interventions relating to them are recorded in the patient medical record. As a result, if a patient is seen in two different services with different medical record systems they will be counted twice in the total number of patients.

PCPSS  Palliative Care Problem Severity Score (PCPSS) is a clinical tool used for initial screening and ongoing coordination of specialist palliative care. Clinician rated, it facilitates the global assessment of four palliative care domains: pain, psychological / spiritual, other symptoms and family / carer.

Phase  Palliative care phase identifies a clinically meaningful period in a patient’s condition. The palliative care phase is determined by a holistic clinical assessment which considers the needs of the patients and their family and carers. The phases provide a framework for referrals, triage and care planning.

RUG-ADL  Resource Utilisation Groups – Activities of Daily Living (RUG-ADL) consists of four items (bed mobility, toileting, transfers and eating) and assesses the level of functional dependence, based on what a person actually does, rather than what they are capable of doing.

SAS  Symptom Assessment Scale (SAS) describes the patient’s level of distress relating to individual physical symptoms. The symptoms in the scale are the seven most commonly experienced by palliative patients; difficulty sleeping, appetite problems, nausea, bowel problems, breathing problems, fatigue and pain. The instrument is designed to be a patient rated tool but also allows for rating by proxy (e.g. family, carer or clinician).
