Inhibition of human N- and T-type calcium channels by an ortho-phenoxylanilide derivative, MONIRO-1

Abstract

Background and Purpose: Voltage-gated calcium channels are involved in nociception in the CNS and in the periphery. N-type (Ca\textsubscript{v}2.2) and T-type (Ca\textsubscript{v}3.1, Ca\textsubscript{v}3.2 and Ca\textsubscript{v}3.3) voltage-gated calcium channels are particularly important in studying and treating pain and epilepsy. Experimental Approach: In this study, whole-cell patch clamp electrophysiology was used to assess the potency and mechanism of action of a novel ortho-phenoxylanilide derivative, MONIRO-1, against a panel of voltage-gated calcium channels including Ca\textsubscript{v}1.2, Ca\textsubscript{v}1.3, Ca\textsubscript{v}2.1, Ca\textsubscript{v}2.2, Ca\textsubscript{v}2.3, Ca\textsubscript{v}3.1, Ca\textsubscript{v}3.2 and Ca\textsubscript{v}3.3. Key Results: MONIRO-1 was 5- to 20-fold more potent at inhibiting human T-type calcium channels, hCa\textsubscript{v}3.1, hCa\textsubscript{v}3.2 and hCa\textsubscript{v}3.3 (IC\textsubscript{50} : 3.3 ± 0.3, 1.7 ± 0.1 and 7.2 ± 0.3 μM, respectively) than N-type calcium channel, hCa\textsubscript{v}2.2 (IC\textsubscript{50} : 34.0 ± 3.6 μM). It interacted with L-type calcium channels Ca\textsubscript{v}1.2 and Ca\textsubscript{v}1.3 with significantly lower potency (IC\textsubscript{50} > 100 μM) and did not inhibit hCa\textsubscript{v}2.1 or hCa\textsubscript{v}2.3 channels at concentrations as high as 100 μM. State- and use-dependent inhibition of hCa\textsubscript{v}2.2 channels was observed, whereas stronger inhibition occurred at high stimulation frequencies for hCa\textsubscript{v}3.1 channels suggesting a different mode of action between these two channels. Conclusions and Implications: Selectivity, potency, reversibility and multi-modal effects distinguish MONIRO-1 from other low MW inhibitors acting on Ca\textsubscript{v} channels involved in pain and/or epilepsy pathways. High-frequency firing increased the affinity for MONIRO-1 for both hCa\textsubscript{v}2.2 and hCa\textsubscript{v}3.1 channels. Such Ca\textsubscript{v} channel modulators have potential clinical use in the treatment of epilepsies, neuropathic pain and other nociceptive pathophysologies.

BACKGROUND AND PURPOSE
Voltage-gated calcium channels are involved in peripheral and central nervous system nociception. N-type (Ca\(_v\)2.2) and T-type (Ca\(_v\)3.1, Ca\(_v\) 3.2 and Ca\(_v\) 3.3) voltage-gated calcium channels are particularly important in studying and treating pain and epilepsy.

EXPERIMENTAL APPROACH
In this study, whole-cell patch clamp electrophysiology was used to assess the potency and mechanism of action of a novel ortho-phenoxyanilide derivative, MONIRO-1, against a panel of voltage-gated calcium channels including Ca\(_v\)1.2, Ca\(_v\)1.3, Ca\(_v\)2.1, Ca\(_v\)2.2, Ca\(_v\)2.3, Ca\(_v\)3.1, Ca\(_v\)3.2 and Ca\(_v\)3.3.

KEY RESULTS
MONIRO-1 was 5-20-fold more potent at inhibiting human T-type calcium channels, hCa\(_v\)3.1, hCa\(_v\)3.2 and hCa\(_v\)3.3 (IC\(_{50}\): 3.3 ± 0.3 μM, 1.7 ± 0.1 μM and 7.2 ± 0.3 μM, respectively) than N-type calcium channel, hCa\(_v\)2.2 (IC\(_{50}\): 34.0 ± 3.6 μM). It interacts with L-type calcium channels Ca\(_v\)1.2 and Ca\(_v\)1.3 with significantly lower potency (IC\(_{50}\) >100 μM), and does not inhibit hCa\(_v\)2.1 or hCa\(_v\)2.3 at concentrations as high as 100 μM. Interestingly, state- and use-dependent inhibition of hCa\(_v\)2.2 was observed, whereas stronger inhibition occurred at high stimulation frequencies for hCa\(_v\)3.1 suggesting a different mode of action between these two channels.

CONCLUSIONS AND IMPLICATIONS
Selectivity, potency, reversibility and multi-modal effects distinguish MONIRO-1 from other small molecule inhibitors acting on Ca\(_v\) channels involved in pain and/or epilepsy pathways. For both hCa\(_v\)2.2 and hCa\(_v\)3.1, high frequency firing increases the affinity for MONIRO-1 for both channels. Such Ca\(_v\) channel modulators have potential clinical use in the treatment of epilepsies, neuropathic pain and other nociceptive patho-physiologies.

INTRODUCTION

Sensory nerve conduction relies on the coordinated activation of a suite of ion channels to generate fast and accurate responses to mechanical, thermal and chemical stimuli. In the periphery, harmful signals are perceived by ‘nociceptive’ neurons and relayed centrally via voltage-activated ion channels (K\textsubscript{v}, Na\textsubscript{v}, Ca\textsubscript{v}) and ligand-gated ion channels (TRP, K2P, P2X) (Waxman et al., 2014) as part of the ‘pain-signalling cascade’ (Gold et al., 2010). In chronic pain, these pathways are characterized by hyperactivity (Waxman et al., 2014) and the effects of noxious stimuli are enhanced (hyperalgesia) to the point where non-noxious stimuli are painful (allodynia) (see recent review by Guo and Hu (Guo et al., 2014)). Voltage-gated calcium channels (VGCCs) involved in pain pathways are localized to dendrites of primary sensory neurons and contribute to integrate nociceptive stimuli at the spine by regulating the release of pro-nociceptive neurotransmitters, including substance P, calcitonin gene-related peptide and glutamate, at the presynaptic nerve terminus (Simms et al., 2014). Therefore, modulating specific Ca\textsubscript{v} subtypes could be a promising way to treat chronic pain.

Five distinct voltage-gated calcium current types have been described in mammalian cells: L- (Ca\textsubscript{v}1.1-1.4), P/Q- (Ca\textsubscript{v}2.1), N- (Ca\textsubscript{v}2.2), R- (Ca\textsubscript{v}2.3) and T- (Ca\textsubscript{v}3.1-3.3) types (Catterall et al., 2005). Importantly, each Ca\textsubscript{v} subtype has distinct electrophysiological properties, tissue-specific localization and pharmacological profiles (Catterall et al., 2005). N-type calcium channels have been a major focus of research because they are localized at the presynaptic terminals of sensory nerves in the dorsal horn of the spinal cord, where they play a critical role in pain signalling (Lee, 2014; Saegusa et al., 2001). As a result, Ca\textsubscript{v}2.2 channels are strongly implicated in a range of chronic pain conditions including neuropathic pain (pain caused by injury to the nervous system). Specific Ca\textsubscript{v}2.2 channel inhibitors have clinical applications (Altier et al., 2004; Bourinet et al., 2014; Perret et al., 2009), such as ω-conotoxin MVIIA (Ziconotide). Ziconotide selectively targets Ca\textsubscript{v}2.2 channels and is used to effectively treat intractable chronic pain conditions (Pope et al., 2013). However, due to its chemical nature, Ziconotide must be administered into the cerebrospinal fluid via the intrathecal route and has a relatively narrow therapeutic window (Pope et al., 2013).
T-type calcium channels modulate neuronal excitability in the peripheral and central nervous systems, where they are linked to hyperexcitable states such as epilepsy, pain and tremor disorders like Parkinson’s disease (Bourinet et al., 2005; Choi et al., 2007; Kim et al., 2001). Previously characterized T-type calcium channels inhibitors, such as mibefradil and ethoximide, have analgesic properties, suggesting that T-type channels may be involved in pain signalling (Flatters et al., 2004; Matthews et al., 2001; Todorovic et al., 2002; Wen et al., 2010). Unfortunately, mibefradil and ethoximide target a wide range of voltage-gated ion channels, including sodium, potassium and chloride channels (Chouabe et al., 1998; Eller et al., 2000; Nilius et al., 1998).

To overcome this lack of specificity, small molecule T-type calcium channel inhibitors were designed and have been shown to provide analgesic effects in mouse models of inflammatory and neuropathic pain (Bladen et al., 2015; Kraus et al., 2010; Reger et al., 2011). Of particular note is the analgesic, small molecule TTA-A2, which is more potent against inactivated than closed or resting channels (IC$_{50}$ values of 100 nM and 10 µM at Ca$_{v}$3.1, respectively), indicating its effects on targets are state-dependent (Francois et al., 2013). Based on these findings, N- and T-type calcium channels are of particular interest for the study and treatment of pain (see recent reviews by (Cheong et al., 2013; François et al., 2014; Lee, 2014; Lee, 2013; Sekiguchi et al., 2013; Simms et al., 2014).

During the last five years, numerous reports have described small molecule Ca$_{v}$2.2 channel inhibitors as alternatives to Ziconotide (see review by Lee (Lee, 2014)). Regrettably, clinical development of the most promising of these small-molecules, Z160, a reformulated form of NP118809 (Zamponi et al., 2009) (compound 1, Fig. 1), was discontinued after it failed to meet end points in phase II clinical trials (Eller et al., 2000). Due to this and the need for effective and safe therapeutics for chronic pain, the development of new classes of small-molecule Ca$_{v}$ channel antagonists is of significant interest.

The pharmacophore of Ca$_{v}$2.2-selective ω-conotoxin GVIA (Andersson et al., 2009; Baell et al., 2004; Baell et al., 2006; Duggan et al., 2009; McCleskey et al., 1987) has been carefully studied and has led to the identification of a series of compounds that block Ca$_{v}$2.2 channels in a concentration-dependent manner (Tranberg et al., 2012).
We focused on developing low molecular weight calcium channel inhibitors with enhanced biophysical properties including reversibility, voltage- and/or state-dependence. Compounds acting via these mechanisms can strongly inhibit channels upon membrane depolarization (Butterworth et al., 1990; Hondeghem et al., 1984) by preferentially targeting the open and/or inactivated states over the resting state. Such compounds would facilitate inhibition of high-frequency firing or depolarised nerves that can predominate in chronic pain states, and could act within a wider therapeutic window.

To develop these calcium channel inhibitors, we screened a small library of related derivatives, using FLIPR Tetra® high-throughput cellular screening system, for their ability to inhibit Ca\text{v}2.2-mediated calcium responses in SH-SY5Y cells using the fluorescent indicator Calcium 4 dye (Molecular Devices, Sunnyvale, CA, USA) (Gleeson et al., 2015). In this assay, MONIRO-1 inhibited Ca\textsuperscript{2+} responses elicited by KCl-mediated depolarization with an IC\textsubscript{50} of 124 µM. Subsequently, we characterized the ortho-phenoxyanilide derivative MONIRO-1 (Compound 2, Fig. 1) electrophysiologically. To directly assess the biophysical properties of MONIRO-1 inhibition of voltage-gated calcium channels, we used the whole-cell patch clamp recording technique to study a comprehensive array of Ca\textsub{v} channels heterologously or stably expressed in HEK-293 cells. MONIRO-1 was 5–100 times more potent against T-type calcium channels (Ca\textsub{v}3.1, Ca\textsub{v}3.2 and Ca\textsub{v}3.3) than N-type (Ca\textsub{v}2.2) and L-type (Ca\textsub{v}1.2 and Ca\textsub{v}1.3) channels. No inhibition of P/Q (Ca\textsub{v}2.1) or R-type currents (Ca\textsub{v}2.3) was detected in the presence of up to 100 µM MONIRO-1. Furthermore, MONIRO-1 modulated Ca\textsub{v}2.2 differently at various stimulation rates and in a state-dependent fashion, preferentially inhibiting hyperactive channels such as those likely to predominate in pathologically augmented pain states.

1. METHODS

1.1 Chemical synthesis.

Compound 2, N-(2-(4-fluorophenoxy)phenyl)-4-(3-guanidinopropoxy)benzamide hydrochloride, MONIRO-1, was synthesized from 2-(4-fluorophenoxy)aniline in four steps, as reported previously (Gleeson et al., 2015). \(^{1}\)H NMR (400 MHz, CD\textsubscript{3}OD): δ 7.88-7.85 (m, 1H), 7.78-7.76 (m, 2H), 7.21-7.18 (m, 2H), 7.07-6.98 (m, 6H), 6.97-6.94 (m, 1H), 4.13 (t, \(J = 5.9\) Hz, 2H), 3.41 (t, \(J = 6.8\) Hz, 2H), 2.11-2.05 (m, 2H). \(^{13}\)C
NMR (100 MHz, CD$_3$OD): $\delta$ 168.2, 163.2, 160.2 (d, $J = 239$ Hz), 158.7, 154.4, 151.0, 130.5, 130.4, 127.9, 127.6, 126.9, 125.0, 120.8 (d, $J = 8.3$ Hz), 120.1, 117.2 (d, $J = 23.4$ Hz), 115.4, 66.3, 39.5, 29.5. $^{19}$F NMR (376 MHz, CD$_3$OD): $\delta$ -120.6, purity $>$ 92%, determined by HPLC analysis ($\lambda = 254$ nm), all tests were performed using the same batch of compound. The positive control, compound 1 (Z160/NP118809) (Zamponi et al., 2009; Zikolova et al., 1972), was prepared by N-(3-dimethylaminopropyl)-N′-ethylcarbodiimide-assisted acylation of N-benzhydryl piperazine with 3,3-diphenylpropanoic acid. Control compound NNC 55-0396 dihydrochloride was provided by Alomone Labs (Jerusalem, Israel).

1.2 Cell culture and transfection.

HEK293 cells containing the SV40 Large T-antigen (HEK293T) were cultured at 37 °C, 5% CO$_2$ in Dulbecco’s Modified Eagle’s Medium (Invitrogen Life Technologies, Australia) supplemented with 10% fetal bovine serum (Invitrogen), 1% penicillin and streptomycin (Invitrogen). HEK293T cells stably expressing the human Ca$_v$2.1 (P/Q-type) calcium channel ($\alpha_{1A-2}$ splice variant; GenBank accession no. AF004883.1), Ca$_v$2.2 (N-type) calcium channel (transcript variant 1, NM_000718) or Ca$_v$2.3 (R-type) calcium channel (neuronal $\alpha_{1E-3}$ splice variant, also called $\alpha_{1E-c}$, L29385.1) were obtained from Merck and cultured according to procedures described by Dai et al. (Dai et al., 2008). These cell lines co-express recombinant human Ca$_v$ $\alpha_{2b}\delta-1$ (M76559.1) and Ca$_v$$\beta_{3a}$ (NM_000725) auxiliary subunits (Dai et al., 2008). Cells are plated onto 12 mm cover glass and incubated at 30 °C, 5% CO$_2$ for 24-48 hours prior to recording.

In a separate series of experiments, HEK293T cells were transiently co-transfected with plasmid cDNAs encoding human Ca$_v$1.3 (provided by Dr G. Zamponi, University of Calgary) with $\alpha_{2b}\delta-1$ and $\beta_3$, Ca$_v$3.1 (provided by Dr G. Zamponi), human Ca$_v$3.2 (CACNA1HB; Origene Technologies, Rockville, MD), human Ca$_v$3.3 a1Ic-HE3-pcDNA3 was a gift from Edward Perez-Reyes(Gomora et al., 2002) (Addgene plasmid # 45810) and K$_v$11.1 (hERG) (provided by Dr J. Vandenberg, Victor Chang Cardiac Research Institute, Sydney). After transfection, cells were plated on glass coverslips and incubated at 37 °C, 5% CO$_2$ overnight. The transfection medium was then replaced with culture medium and cells were incubated at 30 °C, 5% CO$_2$. 

1.3 Electrophysiology.

Electrophysiological experiments were carried out 1-3 days after transfection using the whole-cell patch clamp recording technique. Cells were superfused with a solution containing 110 mM NaCl, 10 mM CaCl$_2$, 1 mM MgCl$_2$, 5 mM CsCl, 30 mM TEA-Cl, 10 mM d-glucose and 10 mM HEPES, pH 7.4 with TEA-OH (∼310 mOsmol/kg). Fire-polished borosilicate patch pipettes with tip-resistance values of 1–3 MΩ were filled with an intracellular solution containing 125 mM Kgluconate, 5 mM NaCl, 2 mM MgCl$_2$, 5 mM EGTA, 4 mM MgATP and 10 mM HEPES, pH 7.2 with CsOH (∼300 mOsmol/kg). Depolarization-activated calcium currents were recorded at room temperature (21-23 °C) using a Multiclamp 700B patch clamp amplifier (Molecular Devices, Sunnyvale, CA) controlled by DigiData 1322/Clampex 9.2 acquisition systems. MONIRO-1 stock solution was dissolved in 5% DMSO to a concentration of 5 mM. MONIRO-1 was further diluted in recording solution to appropriate concentrations. Previous experiments using the maximal concentration of DMSO used, 0.1% at 100 µM, did not modulate VGCC currents in recording solution.

Depolarization-activated calcium currents (I$_{Ca}$) were evoked from a holding potential of −80 mV, with a 135 ms (50 ms for T-type) voltage step to a test potential (determined from peak of I-V curve) applied every 10 s. When evaluating I$_{Ca}$ amplitude in the presence and absence of various compounds, test depolarizations of varying durations were applied at a frequency of 0.03–2 Hz, from a holding potential of −60, −80 or −100 mV to a test potential determined from an I-V relationship to elicit peak inward current. To examine the effects of pulse duration on MONIRO-1 block and recovery from block, pulses of either 45 or 135 ms for Ca$_{v}$2.2 (30 µM) or 15 or 50 ms for Ca$_{v}$3.1 (3 µM) were elicited at a frequency of 0.1 Hz ($V_h = −80$ mV).

Similarly, to study the frequency dependence of MONIRO-1 inhibition, test pulses (45 ms for Ca$_{v}$2.2 or 15 ms for Ca$_{v}$3.1) were elicited at rates of 0.03, 0.1 and 0.2 Hz for Ca$_{v}$2.2 (10 µM MONIRO-1) and 0.03, 0.1, 0.2, 1 and 2 Hz for Ca$_{v}$3.1 (3 µM MONIRO-1). To determine the time constants for activation and inactivation of macroscopic currents, we used a single exponential equation to fit the traces in control and after MONIRO-1 application.

Activation curves were measured from test pulses from -80 to +80 mV every 5 mV for Ca$_{v}$2.2 and Ca$_{v}$3.1 channels ($V_h = −80$ mV) before and after MONIRO-1 application. Steady-state inactivation (SSI) curves were generated from various pre-
pulse potentials (−120 to 0 mV for Ca\textsubscript{v2.2}; −85 to −20 mV for Ca\textsubscript{v3.1}) of 10 s (Ca\textsubscript{v2.2}) or 1 s (Ca\textsubscript{v3.1}). Recovery from inactivation was examined using a double-pulse protocol, varying the time between a fully inactivating prepulse and the test pulse repeated every 15 s, using a concentration of MONIRO-1 which inhibits ~50% of the current. Recovery data was best fit by a double exponential. Currents were filtered at 3 kHz and sampled at 10 kHz. Leak and capacitive currents were subtracted using a −P/4 pulse protocol. Data were stored digitally on a computer for further analysis.

1.3 Data analysis.
Data analysis and graphs were built using OriginPro (Origin Lab Corporation, North Hampton, MA, USA). Concentration-response curves were generated by plotting current in the presence of MONIRO-1 (I_{compound}) over current prior to application (I_{control}) versus a range of MONIRO-1 concentrations tested. Typically, 4-6 concentrations per channel were screened with 5-9 cells per concentration. Concentration-response data was plotted using a rectangular hyperbola assuming a Hill coefficient of 1, using the following expression,

$$(I_{compound}/I_{control}) = 1/(1+IC_{50}/[drug]),$$

where IC\textsubscript{50} is the concentration at which half-maximal inhibition was observed.

Steady-state activation and inactivation curves were generated using a modified Boltzmann equation,

$$G = 1/(1+exp((V_m-V_{0.5})/\kappa a)),$$

where $V_m$ is the test potential, $V_{0.5}$ is the half-maximal activation potential and $\kappa a$ is the slope factor. SSA and SSI data were each recorded from 5-7 individual experiments per channel examined. Recovery from inactivation curves were the results from 5-6 independent experiments where the complete set of recovery from inactivation time points were acquired. The data was fit using a double exponential of the following equation,

$$I = 1+A_{fast} \times \exp(-t/\tau_{fast}) + A_{slow} \times \exp(-t/\tau_{slow}),$$

where $\tau$ is the fast and slow time constant, $t$ is the recovery time and $A$ is the amplitude of the fast and slow time constants. Statistical significance of $P < 0.05$ was determined using unpaired Student’s t-tests or one-way ANOVA using Tukey post hoc test. All data reported as mean ± standard error.
2. RESULTS

3.1 Selective inhibition of human N- and T-type calcium channel subtypes.

Whole-cell calcium currents were elicited by depolarizing pulses at a frequency of 0.1 Hz from a holding potential of −80 mV. MONIRO-1 reversibly inhibited channel currents mediated by Ca\textsubscript{v}3.2 (IC\textsubscript{50} 1.7 ± 0.1 µM, n = 5-9 cells/concentration), Ca\textsubscript{v}3.1 (IC\textsubscript{50} 3.3 ± 0.3 µM, n = 5-6 cells/concentration), Ca\textsubscript{v}3.3 (IC\textsubscript{50} 7.2 ± 0.3 µM, n = 5 cells/concentration) and Ca\textsubscript{v}2.2 (IC\textsubscript{50} 34.0 ± 3.6 µM, n = 5-7 cells/concentration) (Fig. 2 and 3A). The effects of MONIRO-1 were further investigated on a panel of VGCCs. At 100 µM, MONIRO-1 had no apparent effect on Ca\textsubscript{v}2.1 (n = 5) or Ca\textsubscript{v}2.3 (n = 5) (Fig. 3B), but inhibited Ca\textsubscript{v}1.2 and Ca\textsubscript{v}1.3-mediated currents by 45.8 ± 0.9% (n = 5) and 27.0 ± 1.2% (n = 5), respectively.

In comparison, Z160/NP118809 (Zamponi et al., 2009) inhibited Ca\textsubscript{v}2.2-mediated currents with an IC\textsubscript{50} of 0.28 ± 0.02 µM (n = 5-6 cells/concentration), without affecting Ca\textsubscript{v}3.1 currents (maximal concentration tested 1 µM, Table 1). Application of 10 µM NNC 55-0396, a T-type calcium channel inhibitor, inhibited hCa\textsubscript{v}3.2 currents by 96 ± 3% (n = 5). Furthermore, Z160/NP118809 inhibited hERG channels with an IC\textsubscript{50} of 7.4 µM (Zamponi et al., 2009) whereas 100 µM MONIRO-1 did not inhibit hERG channel-mediated K\textsuperscript{+} currents (Table 1). Table 1 compares the IC\textsubscript{50} values obtained for MONIRO-1 inhibition of L-, P/Q-, N-, R- and T-type calcium channels and the hERG potassium channel, with that of the control compounds, Z160/NP118809 and NNC 55-0396, and other known N- and T-type calcium channel inhibitors where electrophysiology data was obtained across a large portion of the voltage-gated calcium channel subtypes.

The current inhibition properties varied between the different MONIRO-1-sensitive Ca\textsubscript{v} subtypes, so we analysed the interaction between MONIRO-1 and T-type (Ca\textsubscript{v}3.1) and N-type (Ca\textsubscript{v}2.2) calcium channels.

3.2 Differential modulation of N- and T-type calcium channels: dependence on frequency and holding potential.

We examined the inhibitory characteristics of MONIRO-1 at different test pulse durations and frequencies on Ca\textsubscript{v}2.2 (Fig. 4A-B) and Ca\textsubscript{v}3.1 (Fig. 5A-B), as representatives of the VGCC types targeted by MONIRO-1. Ca\textsubscript{v}2.2 currents in response to shorter (45 ms) depolarizations were 1.5-times more sensitive to MONIRO-1 inhibition than those elicited by a longer (135 ms) pulse. Channels held
open by the longer pulse also recovered more completely from block (82 ± 9%, n = 5) than those briefly opened (45 ms; 47 ± 3%, n = 5) (Fig. 4A). In agreement with these findings, higher frequency stimulation of Ca\textsubscript{v}2.2 channels rendered a population of channels that was more potently inhibited by MONIRO-1 (0.03, 0.1 and 0.2 Hz; Fig. 4B). At a frequency of 0.2 Hz, MONIRO-1 inhibited Ca\textsubscript{v}2.2 current by 29 ± 1% (n = 5), whereas at 0.1 and 0.03 Hz, only 21 ± 1% (n = 5) and 16 ± 1% (n = 5) of the current amplitude was inhibited, respectively. Interestingly, the effects of MONIRO-1 on Ca\textsubscript{v}2.2 channels are in marked contrast to its effects on Ca\textsubscript{v}3.1 channels (Fig. 5A-B). In the case of Ca\textsubscript{v}3.1, pulse duration did not affect Ca\textsubscript{v}3.1-mediated current inhibition (% block 15 ms: 43 ± 3%, n = 5; and 50 ms: 51 ± 7%, n = 5), recovery from inhibition (% recovery 15 ms: 95 ± 1.3%, n = 5; and 50 ms: 99 ± 0.8%, n = 5) or frequency dependence of block over the same range as those tested for Ca\textsubscript{v}2.2 (% block at 0.2 Hz = 43 ± 1.5%, n = 5; 0.1 Hz = 42 ± 2.3%, n = 5; and 0.03 Hz = 44 ± 1.6%, n = 5). However, at faster rates of 1 and 2 Hz, there was a significant increase in MONIRO-1 block of Ca\textsubscript{v}3.1 (% block at 1 Hz = 61.0 ± 1.5%, n = 6; and 2 Hz = 71.0 ± 2.0%, n = 5). This would increase 3-fold the affinity for channels firing at faster frequencies of 2 Hz compared to those firing at rates <0.2 Hz.

To further explore the differential effects of MONIRO-1 on Ca\textsubscript{v}2.2 and Ca\textsubscript{v}3.1 channels, we investigated the effect of membrane holding potential on block of Ca\textsubscript{v}2.2 and Ca\textsubscript{v}3.1. MONIRO-1 could more effectively block Ca\textsubscript{v}2.2 channels at more depolarized potentials (block at −100 mV = 34 ± 1.8%; −80 mV = 43 ± 3.2%; and −60 mV = 77 ± 5.5%, n = 5). In contrast, block at all of the holding potentials tested did not affect the degree by which MONIRO-1 inhibited Ca\textsubscript{v}3.1 channels (block at −100 mV = 41 ± 0.5%; −80 mV = 46 ± 5.1%; and −60 mV = 43 ± 0.6%, n = 5) (Fig. 4C and 5C). This result highlights the state-dependent differences between MONIRO-1 inhibition of Ca\textsubscript{v}2.2 and Ca\textsubscript{v}3.1 channels.

3.3 Effects of MONIRO-1 on N- and T-type calcium channel activation, inactivation and recovery from inactivation.

To identify any effects MONIRO-1 may have on calcium current kinetics and understand the mechanisms behind the enhanced inhibition at depolarised membrane potentials, we examined its effects at half-maximal concentrations on Ca\textsubscript{v}2.2 and Ca\textsubscript{v}3.1 activation and SSI (Fig. 4D and 5D). Exposure to MONIRO-1 did not affect
the voltage-dependence of activation of Ca\textsubscript{v}2.2 (control $V_{0.5} = 12.5 \pm 0.5$ mV, $n = 5$; MONIRO-1 $V_{0.5} = 12.4 \pm 0.4$ mV, $n = 5$, respectively) or Ca\textsubscript{v}3.1 (control $V_{0.5 \text{ act}} = -34.0 \pm 0.4$ mV, $n = 7$; MONIRO-1 $V_{0.5 \text{ act}} = -34.4 \pm 0.6$ mV, $n = 7$) (Table 2). However, there was a significant ~10 mV hyperpolarizing shift in Ca\textsubscript{v}2.2 SSI (control $V_{0.5 \text{ inact}} = -41.3 \pm 0.7$ mV, $n = 5$; MONIRO-1 $V_{0.5 \text{ inact}} = -52.9 \pm 1.3$ mV, $n = 5$; $P < 0.05$). An apparent decrease in the voltage-dependence of SSI was also seen (control slope factor, $5.3 \pm 0.6$, $n = 5$; MONIRO-1 slope factor, $10.2 \pm 1.2$, $n = 5$; $P < 0.05$). However, no significant changes were observed in Ca\textsubscript{v}3.1 SSI in the presence of MONIRO-1 (control $V_{0.5 \text{ inact}} = -53.5 \pm 0.6$ mV, $n = 6$; MONIRO-1 $V_{0.5 \text{ inact}} = -55.1 \pm 0.6$ mV, $n = 6$) or voltage-dependence of SSI (control slope factor, $4.4 \pm 0.6$, $n = 6$; MONIRO-1 slope factor, $6.1 \pm 0.5$, $n = 6$). Channel activation and inactivation time constants were examined in the absence and presence of MONIRO-1 on Ca\textsubscript{v}2.2 (30 µM) and Ca\textsubscript{v}3.1 (3 µM). MONIRO-1 has no effect on either the activation or inactivation time constants of Ca\textsubscript{v}2.2 (Table 2). However, MONIRO-1 application increased both activation (control: $1.90 \pm 0.08$ ms, $n = 5$; MONIRO-1: $3.45 \pm 0.51$ ms, $n = 5$; $P < 0.05$) and inactivation time constants (control: $10.78 \pm 0.52$ ms, $n = 5$; MONIRO-1: $17.91 \pm 0.74$ ms, $n = 5$, $P < 0.05$) (Table 2).

Finally, we investigated the effect of MONIRO-1 on Ca\textsubscript{v}2.2 and Ca\textsubscript{v}3.1 channel recovery from inactivation. MONIRO-1 had no observed effect on Ca\textsubscript{v}2.2 recovery from inactivation time constants or their relative contribution to either time constants (control $\tau_{\text{fast}} = 0.22 \pm 0.1$ s, $A_{\text{fast}} = 57 \pm 8.5\%$; $\tau_{\text{slow}} = 2.8 \pm 0.7$ s, $A_{\text{slow}} = 45 \pm 8.6\%$; MONIRO-1 $\tau_{\text{fast}} = 0.14 \pm 0.1$ s, $A_{\text{fast}} = 43 \pm 7.0\%$; $\tau_{\text{slow}} = 2.4 \pm 0.4$ s, $A_{\text{slow}} = 58 \pm 6.2\%$, $n = 5$ respectively). However, MONIRO-1 slowed Ca\textsubscript{v}3.1 recovery from inactivation by decreasing the relative contribution of the fast recovery time constant while increasing the contribution of the slow time constant (control $\tau_{\text{fast}} = 0.051 \pm 0.008$s, $A_{\text{fast}} = 80.1 \pm 5.1\%$; $\tau_{\text{slow}} = 0.20 \pm 0.11$ s, $A_{\text{slow}} = 21.8 \pm 5.4\%$; MONIRO-1 $\tau_{\text{fast}} = 0.026 \pm 0.007$s, $A_{\text{fast}} = 29.6 \pm 4.2\%$; $\tau_{\text{slow}} = 0.33 \pm 0.03$s, $A_{\text{slow}} = 70 \pm 4.1\%$, $n = 6$; $P < 0.05$). Therefore, MONIRO-1 can inhibit Ca\textsubscript{v}3.1 more efficiently at firing frequencies > 1 Hz (Fig. 5B), as indicated by the slowed recovery from inactivation and frequency dependence, such as those prevailing in hyperexcitable neurons (Cain et al., 2010).
3. DISCUSSION

In this study, we examined the effects of an *ortho*-phenoxyanilide on the inhibition and biophysical properties of VGCCs. This *ortho*-phenoxyanilide, MONIRO-1, is a low molecular weight compound and was selected for its ability to inhibit VGCCs in a high-throughput calcium influx assay (Gleeson et al., 2015). To ascertain its selectivity and mode of action, we examined its potency of block and biophysical properties on a variety of VGCCs. MONIRO-1 was shown to be a N- and T-type calcium channel inhibitor with advantageous biophysical properties, including state- and use-dependence. It specifically targets Ca_{3.2} and Ca_{2.2}, which have been implicated in various pain pathways, and Ca_{3.1}, which is involved in cell signalling and epilepsy (Choi, 2013; Waxman et al., 2014).

Given that MONIRO-1 inhibits depolarization-activated calcium responses from SH-SY5Y cells (Gleeson et al., 2015), we determined its efficacy and selectivity against several VGCCs expressed in HEK293 cells. After screening representative members of each voltage-gated calcium channel family (L-, N-, P/Q-, R- and T-types), we established that MONIRO-1 preferentially inhibits T-type channels (Ca_{3.1}, Ca_{3.2} and Ca_{3.3} channels), modestly interacts with N-type Ca_{2.2} channels (with 5–20 times less affinity compared to T-type calcium channels), and has poor efficacy for L-type (Ca_{1.2} and Ca_{1.3} channels IC_{50} > 100 µM). No other VGCCs investigated (P/Q-type Ca_{2.1}; R-type Ca_{2.3}) responded to high concentrations of MONIRO-1. hERG, a typical off-target channel of small molecules was not modulated by MONIRO-1 at concentrations up to 100 µM. Subsequently, we characterized the mechanism of MONIRO-1 inhibition on its primary targets, N- and T-type calcium channels.

In the present study, MONIRO-1 inhibited Ca_{3.1} with an IC_{50} of 3 µM, so we examined the mechanistic details of this inhibition. Many T-type calcium channel inhibitors have been identified in assays looking for inactivation state-dependent inhibitors. These studies have led to compounds that predominantly bind and alter steady-state inactivation, including TTA-A2, A-1048400 and NNC 55-0396, unlike MONIRO-1, which does not affect steady-state inactivation of Ca_{3.1}. MONIRO-1 (3 µM) significantly slowed down both channel activation and inactivation kinetics without discernible effects of MONIRO-1 on both V_{0.5act} and V_{0.5inact}. MONIRO-1
slowed recovery of Ca\textsubscript{v}3.1 from inactivation at rates $>$1 Hz which was reflected as an increase in current inhibition at 1 and 2 Hz (Figure 5B,E) suggesting that MONIRO-1 would preferentially target epileptic firing neurons over normal firing neurons. Taken together, the lack of effect of MONIRO-1 on other biophysical properties examined, including the lack of effect of holding potential, suggests that it acts by binding to prevent Ca\textsubscript{v}3.1 channels from transitioning from a non-conducting state to the open state. Therefore, the prolonged recovery from inactivation caused by MONIRO-1 inhibition of Ca\textsubscript{v}3.1-mediated currents is likely due to the slower dissociation of the compound from the open-blocked channels, or due to it accelerating channel transitions into a slow inactivated channel conformation. A similar phenomenon has been observed for mibebradil inhibition of Ca\textsubscript{v}2.1 channels (Timin et al., 2004). 

Ca\textsubscript{v}3.1 channels are key players in the circuitry involved in sleep including the reticular thalamic nucleus, thalamic relay neurons and neocortical pyramidal cells (Chen et al., 2014). Ca\textsubscript{v}3.1 channels are highly expressed in thalamocortical neurons (Kim et al., 2001; Song et al., 2004), where they initiate entry of these neurons into bursting mode – a typical activity mode in absence seizures (Cain et al., 2013). Consequently, Ca\textsubscript{v}3.1 has been directly linked to absence epilepsies (Kim et al., 2001). Disease mutations in Ca\textsubscript{v}3.2 have also been linked to both rat models and human idiopathic generalized epilepsies (Khosravani et al., 2005; Powell et al., 2009) suggesting that inhibitors of both Ca\textsubscript{v}3.1 and Ca\textsubscript{v}3.2 could decrease neuronal firing induced by hyperactivity of these channels during epilepsy. Compound Z944, which has higher affinity for the inactivated state of T-type calcium channels over the resting state, reduced seizure activity in terms of time spent in seizure and the total number of seizures per hour (Tringham et al., 2012). During burst firing, VGCCs repetitively open and close at frequencies of 5-10 Hz (Cain et al., 2010). Ideally, an anti-epileptogenic drug targeting Ca\textsubscript{v}3.1 or Ca\textsubscript{v}3.2 channels in epileptogenic foci, that is, on neurons in bursting mode where the channels are in the open state. Our results suggest that MONIRO-1 modulates Ca\textsubscript{v}3.1 channels by holding the channel in a non-conducting state thus prolonging recovery from inactivation, which makes the compound well suited for the study and/or potentially for the amelioration of Ca\textsubscript{v}3.1 or Ca\textsubscript{v}3.2-mediated epileptogenesis in neurons entering bursting mode.

Considerable research into pain physiology has focused on voltage-gated N- and T-type calcium channels. Ca\textsubscript{v}3.2 channels are expressed in peripheral sensory neurons,
where they modulate pain processing by controlling dorsal root ganglion neuroexcitability (Carbone et al., 1984). Ca$_{v}2.2$ channels are located at presynaptic terminals in the central nervous system, where they modulate neurotransmitter release and fast synaptic transmission (Wheeler et al., 1994). MONIRO-1 inhibits Ca$_{v}2.2$ under resting state conditions with an IC$_{50}$ of ~30 µM, which is approximately 10-fold higher than that observed the T-type channels. However, the effect of MONIRO-1 on Ca$_{v}2.2$ is enhanced at higher frequencies, where faster pacing of the channel increased inhibition. At frequencies as high as 0.2 Hz (the maximum tested), the apparent affinity increased to ~20 µM, with no observable change to the time course of activation or inactivation of the channel (Fig. 4B and Table 2).

Following this observation, we examined MONIRO-1’s potential state dependence. Short (45 ms) depolarizing test pulses produced greater inhibition of Ca$_{v}2.2$ as well as less recovery after washout compared to a longer (135 ms) test pulse, suggesting a possible decrease in affinity for the open and/or inactivated state (Fig. 4A). MONIRO-1 had a pronounced effect on Ca$_{v}2.2$ channel SSI that was not paralleled in Ca$_{v}3.1$ (Fig. 4D) as well as strong dependence on holding potential. At −60 mV ~80% of the whole-cell current was inhibited compared to −100 mV where only ~35% of the current was blocked (Fig. 4C). Such a hyperpolarizing shift in SSI and the dependence on holding potential suggests that MONIRO-1 preferentially binds to the inactivated state of N-type calcium channels (Bean, 1984; Bean et al., 1983; Sanguinetti et al., 1984). Interestingly, unlike its effect on T-type calcium channels, MONIRO-1 did not influence N-type calcium channel recovery from inactivation (Fig. 5E) suggesting a distinct mode of action against the two channel families.

Nociceptive stimuli cause depolarization, calcium channel opening, intracellular [Ca$^{2+}$] increase and neuronal hyper-excitability evidenced by faster firing rates (Winquist et al., 2005). Nociceptive stimuli reduce the effective open time and increase the frequency of channel opening (Winquist et al., 2005). Sustained neuronal firing in pain syndromes increases cytosolic calcium levels in the dorsal horn and shifts calcium channels into the inactivated state. Therefore, drugs that target Ca$_{v}2.2$ are best suited to ‘prefer’ those in the inactivated state (predominant in pain syndromes), allowing normal neurotransmitter release signalled by these channels in neurons not in a pain state.
A few compounds have recently reported to exhibit use- and/or state-dependent inhibition of calcium channels involved in pain signalling, including A-1048400 (Scott et al., 2012) (compound $3$, Fig. 1), Z160/NP118809 $1$ (Zamponi et al., 2009), and TROX-1 (Abbadie et al., 2010). To explore MONIRO-1 inhibitory mechanism of $\text{Ca}_v2.2$, we examined stimulation conditions comparable with those occurring in the physiological setting. Given that $\text{Ca}_v2.2$ channels can potentially accumulate in the inactivated state in hyperactive pain state conditions (Winquist et al., 2005), the selective effect of MONIRO-1 on channels in this state could be a valuable pharmacological property that would enable therapeutic targeting during neuropathic pain treatment. Frequency dependence and preference of MONIRO-1 for the inactivated $\text{Ca}_v2.2$, suggest that it or related compounds may prove useful in the prevention of high-frequency firing episodes, an important signalling mode occurring during pain transmission. Therefore, MONIRO-1 may preferentially inhibit channels in hyperexcitable states in pain-specific loci, leaving normally firing neurons unaffected (Liao et al., 2011).

4. CONCLUSION

We identified MONIRO-1 as a low molecular weight voltage-gated calcium channel antagonist with $10^{-100}$-fold higher affinity for $\text{Ca}_v3.1$, $\text{Ca}_v3.2$, $\text{Ca}_v3.3$ and $\text{Ca}_v2.2$ than other classes of VGCCs examined. MONIRO-1 is a valuable tool for the study of VGCCs because it inhibits N- and T-type calcium channels through distinct mechanisms. Given its state- and use-dependent inhibition of $\text{Ca}_v2.2$ (preferentially inhibits the inactivated state) and $\text{Ca}_v3.1$ (prohibiting channel transitions to the open state), while exhibiting frequency dependent block of both channels. MONIRO-1 is a novel lead compound that could be used to develop $\text{Ca}_v$ channel blockers to treat VGCC pathologies, including neuropathic pain and epilepsy. MONIRO-1 shows a novel mechanism of block of hCav3.1 compared to previously described T-type calcium channel blockers, in that it slows channel activation and inactivation kinetics and traps channels at high frequency firing (>1 hZ) from transitioning to the open state while not altering steady-state inactivation. Prior to in vivo assessment of their analgesic potential, MONIRO-1 and analogues need to be characterised at other voltage-gated ion channels in pain pathways, including $\text{Na}_v1.7$ and $\text{Na}_v1.8$. 
AUTHOR CONTRIBUTIONS
JRM, PJD, KLT and DJA designed the experiments,
JRM, LM, ECG and SS performed the experiments, JRM analysed the
electrophysiological data,
JRM, PJD, KLT, and DJA prepared the figures,
JRM wrote the manuscript,
JRM, RJL, PJD, KLT, and DJA revised the manuscript.
