Parents' and adolescents' perceived influences and barriers to mental health services

A thesis presented in partial fulfilment of the requirements of the degree of Doctor of Psychology (Clinical) at the University of Wollongong

Tim J. Wahlin

2007
Abstract

Many young people with mental health problems do not seek professional help and remain at risk of suicide and adult psychopathology. The present research investigates the barriers that impede the help seeking of parents and their children and the sources of influence that assist young people to access clinical services. Study 1 uses archival data from a recent survey of non-clinical samples of young people between 15-25 years of age who attended Technical and Further Education (TAFE) colleges (n = 137) or accessed neighbourhood centres (n = 49). Respondents completed measures of psychological distress, suicidal ideation, perceived help seeking barriers and intentions to seek professional help for personal-emotional problems and suicidal thoughts. In TAFE students, psychological and practical barriers were related to intentions to seek help for personal-emotional problems and thoughts of suicide. There was also a positive association between help seeking barriers and the level of suicidal ideation. In the youth centre sample, those in greater distress and therefore most in need, reported more obstacles to obtaining help. There was also evidence of help negation. Higher levels of suicidal ideation were associated with lower levels of intent to seek out professional help.

Study 2 examined the relative influence of parents and others on the decision of a young person to access professional help and the relative strength of the barriers faced by parents seeking help for their children. The sample comprised 122 parents and 131 adolescents who attended an initial clinical assessment interview with a Child and Adolescent Mental Health Service (CAMHS) in Sydney or the Illawarra region of New South Wales. Parents completed measures of help-seeking barriers and influences and the Strength and Difficulties Questionnaire (SDQ; Goodman, 1997). The adolescents completed a measure of help-seeking influences and the self-report SDQ (Goodman, Melzer, & Bailey, 1998).

Ninety-four percent of young people reported that others had influenced their decision to access help. Almost 87% were influenced by multiple sources but parents were the single strongest source of influence. Parents and children indicated that parents were more influential in the decision to seek help when there was greater disagreement between parent and child on the extent of the young person's overall and externalising difficulties on the SDQ. Positive relationships emerged between parent-rated influence
variables and parent scores on the Total Difficulties and Externalising SDQ scales. Youth-rated total and externalising difficulty scores were positively related to greater self-involvement in accessing help.

Parents rated the strongest barriers to accessing help as; help was too expensive, the wait was too long, not knowing where to get help, thinking that they could solve their child's problem without help and, their child not wanting help. The findings are consistent with contemporary process models that suggest help seeking is a social process and that young people in particular are highly dependent on parents to access help (Cauce et al., 2002; Logan & King, 2001). In addition, it highlights the need to better promote local services and in particular increase awareness that public services are no-fee. Providing parents and their adolescents with strategies for managing differences, in perceptions of problem severity, during the waiting period may reduce both the wait time barrier and effects of problem perception discrepancies on the social influence process.
Acknowledgements

My thanks go first to the young people and parents who participated in this research and to the administrative and clinical staff of the Child and Adolescent Mental Health Services of Hornsby Ku-Ring Gai, Ryde and the Illawarra, who so willingly supported me in the collection of data. I am also grateful to Dr. Coralie Wilson for her kind and timely assistance with the archival data used in Study 1.

For his enthusiasm, encouragement and commitment to this project and giving so generously of his time my warm thanks go to Professor Frank Deane.

Finally, I would like to express how much the patience, love, and welcome distractions of my family, Merryl, Sarah and Christopher have sustained me over a journey that started many years ago.

Overview

The Australian nationwide survey of mental health and well-being involving 4,500 children and adolescents from 4-17 years old, found a high prevalence of mental health problems among young people in Australia (Sawyer et al., 2000). However, only 52% of the children and adolescents who were experiencing serious mental health problems had attended any treatment in the preceding six months (Sawyer et al., 2000). There are clear risks associated with untreated mental health problems. First, there is evidence that psychopathology in adolescence increases the risk of having a psychiatric disorder as an adult (Hofstra, van der Ende, & Verhulst, 2001). Second, having mental health problems can significantly increase a person’s risk of suicide. Psychological autopsy studies have consistently shown that 90% of suicide victims in all age groups have had a psychiatric disorder (see Brent, 1995; Gould & Kramer, 2001; Graham et al., 2000). Mood disorders in particular have been implicated as a risk factor for suicide (Graham et al., 2000).

Many young people who may benefit are not seen by clinical services. Therefore, attention must turn to improving our understanding of the processes by which young people do reach clinical care. The present research addresses this need in two related studies. The first study uses archival data from TAFE students and a potentially more marginalised sample of young people accessing neighbourhood youth centres. This study aims to extend past findings on help negation and investigate the impact of level of psychological distress and perceived barriers on the intentions of young people to seek out professional mental health care. The second study involves young people from a clinical population and their parents. The influence of parents and others on the decision of young people to access professional help and the practical and psychological barriers faced by parents seeking help for their child are examined.
