Unlocking the potential of amorphous red phosphorus films as a long-term stable negative electrode for lithium batteries

Abstract

Amorphous red phosphorus films (NS-RP) synthesized by a high energy sonication technique delivered a reversible capacity of 2137 mA h g⁻¹ when used as a sole active lithium battery anode. After incorporation of reduced graphene oxide in NS-RP, the hybrid delivered a reversible capacity of 706 mA h g⁻¹, even after 200 cycles.

Experimental details

All chemicals used were of laboratory grade, purchased from Sigma Aldrich, and used without any further treatment.

Preparation of nanostructured red phosphorus (NS-RP)

NS-RP was prepared from commercial RP by high-energy ultrasonication with an ultrasonic processors (Model: VC505-VC750, Sonics & Materials INC, USA). In a typical synthesis, 1 g of red phosphorus was dispersed in 20 ml distilled water. This solution was then subjected to high-energy sonication for 20 h in an ice-cooled water bath at an amplitude of 35 with 2 s pulse time for each on and off pulse. The temperature of the solution was maintained at < 25 °C by the constant addition of ice cubes into the surrounding water bath. The as-obtained solution was then frozen in a liquid-nitrogen bath and subjected to freeze-drying at -55 °C for 3 days. The product was labelled as NS-RP for further analysis.

Preparation of NS-RP-rGO hybrid

Three different RP – reduced-graphene-oxide (rGO) hybrids containing 10, 20, and 30 wt.% rGO were prepared. Appropriate quantities of NS-RP and rGO were put into 20 ml DD H₂O and subjected to ultrasonication for 3 h at an amplitude of 35 with 2 s pulse time for each on and off pulse. The obtained precursor was freeze-dried at -55 °C for 3 days and labelled as NS-RP@rGO-10, NS-RP@rGO-20, and NS-RP@rGO-30, respectively.

Material characterizations

All samples were subjected to physical and electrochemical characterizations. Phase purities were determined by X ray diffraction (XRD; GBC MMA) with Cu K_α irradiation at 1°/min scan rate and 0.02° step size. Morphologies and their compositions were analysed by field-emission-gun-scanning electron microscopy (FEGSEM, JOEL) operated at 5 V and 10 μA, while particle sizes and particle size distributions were determined by transmission electron microscopy (TEM, JOEL JEM 2010) operated at 200 kV with a resolution of 10 Å and processed with Gatan Micrograph software and nanosheet's depth profile was determined using atomic forced microscopy (AFM, Asylum Research MFP-3D Scanning probe microscopy, SPM). The structures and compositions were also analysed by Raman spectroscopy. X ray photoelectron spectroscopy (XPS) was used to determine the surface composition and the valence states of the respective elements. Nitrogen adsorption-desorption studies were performed with a Quantachrome (iQ-MP) for Brunauer-Emmett-Teller (BET) surface-area analysis.

Electrochemical Characterization

All samples were tested in a classical CR 2032 coin cell in a two-electrode system against Li⁺/Li⁰. A slurry containing an 8:1:1 wt. ratio of active material (NS-RP) to carbon Super P (as conducting agent) to polyvinylidene fluoride (PVDF as binder) was prepared with N-methyl-2-pyrrolidone (NMP), as blending solvent in a planetary mixer. Electrodes were prepared from

the NS-RP@rGO hybrid composites in a weight ratio of 7:1.5:1.5 with carboxymethyl cellulose (CMC) as binder and Super P carbon with DD water as solvent. The obtained slurry was tape cast over copper foil with a doctor blade 50 μm in thickness and vacuum dried at 120 $^{\circ}\text{C}$ (for PVDF binder) and 80 $^{\circ}\text{C}$ (for CMC binder) overnight. The electrodes were cut into disks, and each disk was loaded with 1 $\text{mg}\cdot\text{cm}^{-2}$ active materials, ~ 0.5 mg of active materials. The cells were fabricated in an argon-filled glove box maintained at less than 0.1 ppm O_2 and H_2O and tested as anodes for LIBs. The NS-RP hybrid electrode was used as the working electrode with Li foil as reference/counter electrode separated by Celgard, soaked in a few drops of 1 M LiPF_6 (in 1:1 v/v ethylene carbonate/ diethyl carbonate (EC/DEC)) as electrolyte. All cells were rested overnight to reach equilibrium and exhibited an open circuit voltage of 2.9-3.0 V against Li^+/Li^0 . The cells were tested galvanostatically in an advanced multichannel battery tester (Land CT2001A, China) between 0.002 and 3 V against Li^+/Li^0 . The galvanostatic intermittent titration technique (GITT) measurements consisted of a series of current pulses applied to the coin cells at a low current density of 100 $\text{mA}\cdot\text{g}^{-1}$ for 20 minutes, each followed by a 90 minute recess to allow full relaxation of lithium diffusion, so as to reach equilibrium potential and to minimize the self-discharge of RP during the test. Cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) were conducted with Biologic VMP3 instruments. CV was conducted with scanning at 0.1 $\text{mV}\cdot\text{s}^{-1}$ between 0.002 and 3.00 V, while EIS was conducted by applying a sine wave 5 mV in amplitude over the frequency range of 0.1 MHz to 10 mHz.
