A robust free-standing MoS₂/poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) film for supercapacitor applications

Abstract

Two-dimensional molybdenum disulfide (MoS₂) is a promising energy storage material due to its high surface area and unique electronic structure. Free-standing flexible MoS₂-based electrode is of importance for use in flexible energy storage devices, whereas there are limited reports available. In this work we developed a robust hybrid film, MoS₂ incorporated with highly conductive poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate). This free-standing film possesses excellent mechanical properties with a fracture strength of 18.0 MPa and a Young's modulus of 2.0 GPa. It can deliver a large volumetric capacitance of 141.4 F cm⁻³, a high volumetric energy density of 4.9 mWh cm⁻³, and a capacitance retention rate of 98.6% after 5000 charge/discharge cycles. This film has demonstrated its application in an all-solid-state bendable supercapacitor as well.

Abstract

Two-dimensional molybdenum disulfide (MoS₂) is a promising energy storage material due to its high surface area and unique electronic structure. Free-standing flexible MoS₂-based electrode is of importance for use in flexible energy storage devices, whereas there are limited reports available. In this work we developed a robust hybrid film, MoS₂ incorporated with highly conductive poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate). This free-standing film possesses excellent mechanical properties with a fracture strength of 18.0 MPa and a Young's modulus of 2.0 GPa. It can deliver a large volumetric capacitance of 141.4 F cm⁻³, a high volumetric energy density of 4.9 mWh cm⁻³, and a capacitance retention rate of 98.6% after 5000 charge/discharge cycles. This film has demonstrated its application in an all-solid-state bendable supercapacitor as well.

Key words: molybdenum disulfide, PEDOT:PSS, free-standing film, supercapacitors, conjugated polymer.

1. Introduction

Flexible/bendable electronic equipments such as roll-up displays and wearable devices are currently under rapid development, which urgently requires the development of flexible energy storage devices to match.[1-3] As an important energy storage device, flexible supercapacitor has attracted attention due to its ease of large-scale production and promising electrochemical properties (*i.e.* large capacitance, high power density and long cycle life).[4, 5] Free-standing, binder-free films are one very important type of flexible electrodes, since they can be easily processed into different shapes and sizes for simplicity of device fabrication. Two-dimensional (2D) graphene or conjugated polymers films have demonstrated this use,[6-9] while the pursuit of new materials with higher performance is still in demand.

Molybdenum disulfide (MoS_2) nanosheet, as a typical inorganic analogue of graphene, has emerged as an excellent material for energy storage applications due to its sheet-like structure providing large surface area for charge storage.[10-12] The centre Mo atom in MoS_2 has a wide range of oxidation state from +2 to +6, offering pseudo-capacitances.[13-15] Moreover, MoS_2 is non-toxic, eco-friendly and of low cost.[16]

Li-intercalation exfoliation method is a widely used method to fabricate single- and few-layer MoS_2 nanosheets. The produced high-concentration MoS_2 nanosheets in dispersion are the ideal precursor for fabrication of free-standing MoS_2 films. In addition, these Li-intercalation exfoliated MoS_2 nanosheets contain a high ratio of metallic 1T phase,[17] which can electrochemically intercalate with various ions, resulting in high capacitive performance. The 1T- MoS_2 film via filtration delivered a volumetric capacitance ranging from 400 to 700 F cm^{-3} in aqueous electrolytes.[17] However, this film was used with the aid of a mechanical support of a gold coated substrate. Probably the free-standing film was lacking in mechanical

robustness and flexibility due to the small lateral size of MoS₂ nanosheets (typically < 1 μm) and the relatively low aspect ratio.[18] The large size of liquid-crystal MoS₂ may provide a solution.[19] Moreover, the restacking of MoS₂ nanosheets may result in a poor capacitive performance especially for thick films, due to the loss of surface area. The introduction of supportive materials such as graphene can enhance the mechanical as well as electrochemical properties. For example, three-dimensional MoS₂/graphene aerogel prepared by a hydrothermal procedure could deliver a specific capacitance of 268 F g⁻¹ at 0.5 A g⁻¹. A free-standing and flexible MoS₂/GO hybrid film via vacuum filtration[18] has shown a high volumetric capacitance (~ 380 F cm⁻³ at 10 mV s⁻¹).

Conjugated polymers (CPs) are an intriguing class of materials to form high performance composites with a variety of materials (*e.g.* metal oxides, organic conductors, 2D materials) for supercapacitor applications.[20-22] The composites based on CPs and 2D materials exhibit properties of each of the individual components with synergistic effect due to the facile charge transfer between these two constituents.[23] The addition of CPs to 2D semiconductors (*i.e.* MoS₂ in this work) is valuable because CPs can function as the conducting platform for charge delivery between 2D sheets. The reported composites include MoS₂/polyaniline,[24] MoS₂/polypyrrole[14] and MoS₂/poly(3,4-ethylenedioxythiophene) composites[25], demonstrating high capacitances in the range of 400-700 F g⁻¹. However, these composites are all in the powder form. The reports on free-standing flexible MoS₂-CPs films are still limited. The widely used poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) possesses all the above mentioned advantages for supercapacitor application.[26] More importantly, it can be easily dispersed into different solvents.[27] This unique character allows it to be easily mixed with MoS₂ dispersion forming MoS₂/PEDOT composites and a free-standing flexible film may be produced via simply casting or filtration.

Herein, free-standing MoS₂/PEDOT hybrid films were fabricated through a simple filtration technique. The resultant MoS₂/PEDOT films were robust, demonstrating a high fracture strength of 18.0 MPa. They could deliver high volumetric capacitances and good cycling stability as well. Moreover, this hybrid film had demonstrated its application in all-solid-state bendable devices. This work provides a step forward to the practical application of MoS₂-based electrodes in flexible supercapacitors.

2. Experimental

2.1. Materials

Molybdenum disulfide fine powder was sourced from Asbury Carbon. Poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT: PSS) pellets were obtained from Agfa Group. N-butyllithium (2.5 M solution in hexane) was purchased from Sigma-Aldrich.

2.2. Fabrication of MoS₂ nanosheets in aqueous dispersion

Chemically exfoliated MoS₂ nanosheets were prepared using lithium intercalation-exfoliation method developed by Morrison and co-workers.[28] Briefly, dried MoS₂ powder (1g) was put into a 100 mL round-bottom flask, followed by the addition of 2.5 M n-butyllithium solution (10 mL). This mixture was stirred for 48 h under the protection of argon. Then the Li-intercalated MoS₂ was exfoliated into water (~100 mL) via sonication. The resulting dispersion of exfoliated MoS₂ nanosheets was purified by dialysis with water for 2 weeks, removing the contained lithium ions and organic residues.

2.3. Fabrication of MoS₂/PEDOT hybrid films

The MoS₂ nanosheet dispersion (~1 mg mL⁻¹, 60 mL) was added dropwise to 1.5 wt% PEDOT:PSS dispersions (4 mL, 2 mL or 0.8 mL) under stirring to fabricate the films with a weight ratio of 1:1, 2:1 and 5:1 (MoS₂ : PEDOT:PSS). The mixture was then filtered onto a

PVDF hydrophobic filter membrane (90 mm diameter, pore size of 0.22 μm) and peeled off. The complete incorporation of PEDOT:PSS can be evidenced by the clear filtrate produced during the filtration process, as the dispersion containing tiny amount of PEDOT:PSS is light blue in color. These films were dried in a vacuum oven at 60 $^{\circ}\text{C}$ overnight. They were denoted as MoS₂/PEDOT-1, MoS₂/PEDOT-2 and MoS₂/PEDOT-5 according to the above-mentioned weight ratio. As control samples, neat MoS₂ films were fabricated using the same amount of MoS₂ nanosheets dispersion via the same procedure but on a 47 mm-diameter membrane instead, due to the difficulty in forming robust freestanding films on a 90 mm membrane. Neat PEDOT:PSS films were fabricated by a simple casting technique.

2.4. Structural and morphological characterization

The topographic data of exfoliated MoS₂ nanosheets were collected by atomic force microscopy (AFM) (Asylum Research, MFP-3D). Transmission electron microscopy (TEM) images of MoS₂ nanosheets were collected using JEOL JEM-2200FS. The morphology of the films was characterized with field emission scanning electron microscopy (FE-SEM) (JEOL JSM-7500FA). Raman spectra were obtained with a confocal Raman spectrometer (Jobin Yvon HR800, Horiba) using a 632.8 nm diode laser. X-ray photoelectron spectroscopy (XPS) data was collected from a hemispherical energy PHOIBOS 100/150 analyser. Tensile tests of the films were conducted using a Shimadzu EZ mechanical tester at a cross-head speed of 1 mm/min.

2.5. Supercapacitors assembly and electrochemical measurements

Symmetrical supercapacitors were assembled into two-electrode Swagelok type cells with filter paper as separator and 1 M Na₂SO₄ as electrolyte. The films were cut into a dimension of 0.5 cm $\times$ 0.5 cm for use.

For an all-solid-state supercapacitor, a PVA/H₃PO₄ gel electrolyte (PVA:H₃PO₄, 1:1.5) was used following the previously reported procedure.[29] A film electrode (1 cm × 2 cm) was pasted onto a stainless steel mesh with silver paste (Electron Microscope Sciences Co.), followed by being immersed in the electrolyte overnight. Two electrodes with the semi-dried electrolyte layer were pressed together forming flexible devices.

Cyclic voltammetry (CV) of the device was conducted from 0 to 1 V using a CHI 604D (CHI Instruments). Electrochemical impedance spectra were obtained using a Gamry EIS 3000 system over the frequency range of 100 kHz to 0.01 Hz with an AC perturbation of 10 mV at open circuit potential. Galvanostatic charge/discharge tests of the devices were performed using a battery test system (Neware Electronic Co.) between 0 and 1 V.

3. Results and discussion

The exfoliated MoS₂ nanosheets show a lateral sheet size of 100-200 nm (Fig. 1a). The height profile displays a thickness of around 1.0 nm (Fig. 1b). The nanosheet with a ~2.0 nm thickness can also be observed, indicating a 2-3 layered structure. The thickness of a mechanically exfoliated MoS₂ monolayer is typically 0.65~0.70 nm.[30, 31] The variation in thickness can be ascribed to the surface corrugation due to distortions, the presence of adsorbed or trapped molecules.[32] The TEM image further reveals a layered structure of the exfoliated MoS₂ nanosheets (Figure 1c). A typical few-layer MoS₂ nanosheet can be observed with an average interlayer distance of 0.66 nm.

The pristine PEDOT:PSS film shows a compact and featureless cross-sectional view (Fig. 2a). Within a free-standing MoS₂ film, MoS₂ nanosheets restacked on top of each other forming a typical layered structure (Fig. 2b). With the introduction of PEDOT:PSS into the system, it still retains a layered structure (Fig. 2c-e). At higher magnification, no distinct gaps can be found between the nanosheets assembly within the hybrid film (MoS₂/PEDOT-2) as that for

MoS₂ (Fig. 2f, 2g). This may be explained by that the polymer PEDOT acts as glue connecting MoS₂ sheets together. All the elements Mo, S and C were uniformly distributed within the MoS₂/PEDOT-2 film, as evidenced from the energy dispersive X-ray spectroscopy (EDS) results (Figure S1), indicating the even distribution of PEDOT:PSS in the hybrid film. In comparison, no C element can be detected on the cross-section of the neat MoS₂ film. Neat MoS₂, neat PEDOT:PSS, MoS₂/PEDOT-1, MoS₂/PEDOT-2 and MoS₂/PEDOT-5, demonstrated a respective thicknesses of 9.5 μm , 9.6 μm , 9.3 μm , 7.0 μm and 4.5 μm . The corresponding density (ρ) was 3.56 g cm⁻³, 1.60 g cm⁻³, 1.79 g cm⁻³, 1.96 g cm⁻³ and 2.22 g cm⁻³.

The reinforcement effect of PEDOT:PSS on the mechanical properties of the hybrid films was characterized by tensile tests (Fig. 2f). The neat MoS₂ film displayed very poor mechanical properties with a fracture strength of only 5.3 MPa and a maximum elongation of 0.3%, due to the relatively small lateral size of MoS₂ sheets and lack of strong interactions between the restacked layers. With the incorporation of PEDOT:PSS (~20%), MoS₂/PEDOT-5 film displayed an improved mechanical strength of 7.4 MPa (39.5% increase). The mechanical properties of these hybrid films were dramatically improved with the increased amount of PEDOT:PSS. The MoS₂/PEDOT-1 (~50% PEDOT) and MoS₂/PEDOT-2 (~33% PEDOT) films exhibited a fracture strength of 23.5 MPa and 18.0 MPa, a 341% and 238% increase, respectively. The respective maximum elongation was also increased to 1.4% and 0.9%, a 442% and 262% increase. These films are robust, as demonstrated in Fig. 2f (inset). The detailed mechanical properties are summarized in Table 1 for clarity. The mechanical strength of these two hybrid films (MoS₂/PEDOT-1 and MoS₂/PEDOT-2) is higher than or comparable to that of the previously reported flexible MoS₂ or graphene based films, including MoS₂/GO hybrid film (65 MPa),[18] graphene-cellulose paper (8.67 MPa)[33] and graphene/polypyrrole nanofiber films (35.0 MPa)[34]. Not surprisingly, neat PEDOT:PSS

film possessed the best tensile performance with the highest fracture strength of 35.9 MPa and maximum elongation of 3.8%. The incorporation of PEDOT:PSS, cannot only benefit the mechanical properties, but also enhance the electrical conductivity (Table 1). These hybrid films exhibited at least one order of magnitude higher conductivities (17.9, 11.9 and 4.4 S cm⁻¹ for MoS₂/PEDOT-1, 2 and 5 film) than that of the neat MoS₂ film (0.5 S cm⁻¹). Such improvement may be attributed to enhanced electron transport along the conducting polymer chains that form a conductive matrix within the hybrid film.

The chemical structure of bulk MoS₂, chemically-exfoliated MoS₂ and hybrid films was studied by Raman spectroscopy. Bulk MoS₂ showed two characteristic peaks at 382.2 cm⁻¹ and 406.6 cm⁻¹ (Fig. 3a), which can be assigned to the in-plane (E_{2g}¹) and out-of-plane (A_{1g}) vibration modes, respectively.[35, 36] Upon chemical exfoliation, a blueshift of E_{2g}¹ and A_{1g} peak to 375.5 cm⁻¹ and 402.0 cm⁻¹ was observed for the restacked MoS₂ film, indicating that the exfoliated MoS₂ had undergone partial phase transition from 2H to 1T.[37, 38] These blueshifts can also be found in hybrid films, suggesting that the 1T component of the exfoliated MoS₂ was well maintained after being hybridized with PEDOT:PSS.[32]

X-ray photon spectroscopy (XPS) results further supported this phase transition of MoS₂ before and after exfoliation. In the case of bulk MoS₂, there exists two narrow peaks at 232.8 eV and 229.6 eV in the Mo 3d binding region (Fig. 3b), corresponding to Mo 3d_{3/2} and Mo 3d_{5/2} respectively, indicating the +4 oxidation state of 2H-phase MoS₂.[19, 39, 40] Upon chemical exfoliation, these two peaks are broadened. The deconvolution of these peaks shows two more peaks located at 231.8 eV and 228.5 eV, which suggests that the structure of MoS₂ has partially transformed from 2H phase to 1T phase.[32] The ratio between 1T phase and 2H phase in the exfoliated MoS₂ can be quantified by fitting the deconvoluted peak areas. The 1T:2H ratio in neat MoS₂ film is ~1:1, which means that about half of the 2H-phase MoS₂ have been converted into 1T phase. For the hybrid films similar deconvoluted peaks assigned to

1T-phase MoS₂ can be observed. The 1T:2H ratio in MoS₂/PEDOT-2 film is ~0.96:1, very close to that of neat MoS₂ film, indicating the well-retained structure of exfoliated MoS₂. The oxidation of MoS₂ in these hybrid films can also be noticed, as evidenced by a new small peak at 235.2 eV corresponding to Mo⁶⁺ 3d_{5/2}. [41]

The CV curves of MoS₂/PEDOT-2 hybrid film and neat film electrodes at a scan rate of 50 mV s⁻¹ are illustrated in Fig. 4a. The capacitive performance was investigated in a two-electrode configuration, which is a closer arrangement to a practical device. The MoS₂/PEDOT-2 film exhibited significantly higher current response than neat MoS₂ and PEDOT:PSS, indicating a much higher capacitance to deliver. The densely restacked structure of MoS₂ film could hinder the diffusion of electrolyte ions into the interior of the film, leading to a poor utilization of the material and low capacitance, as demonstrated for graphene-based materials. [42, 43] The presence of highly conductive PEDOT:PSS could not only prevent MoS₂ nanosheets from restacking, but also facilitate the charge delivery between the MoS₂ nanosheets. MoS₂/PEDOT-2 film displayed nearly rectangular CV shapes even at a high scan rate of 100 mV s⁻¹ (Fig. 4b), demonstrating an excellent capacitive behaviour. For neat MoS₂, the distortion of the curves can be clearly seen when the scan rate reaches 50 mV s⁻¹ (Fig. 4c), which may be ascribed to its low conductivity.

The supercapacitors based on MoS₂/PEDOT-2 films showed nearly linear and symmetric charge/discharge curves at the applied current densities range of 0.2 to 4 A g⁻¹ (Fig. 4d), indicating an excellent reversibility. These hybrid films delivered much larger volumetric capacitances than neat MoS₂ or PEDOT:PSS film at a current density of 0.2 A g⁻¹ (Fig. 4e). The current applied was based on the total mass of both film electrodes. The volumetric capacitance of a single electrode was calculated using the equation of $C_V = \rho \times C_g = \rho \times (4 \times i \times t) / (m \times \Delta V)$, where C_V is the volumetric capacitance in F cm⁻³, ρ is the density of the films in g cm⁻³, C_g is the gravimetric capacitance in F g⁻¹, i is the discharge

current in A, t is the discharge time in s, m is the total mass of the two electrodes in g and ΔV is the scan potential window in V. These hybrid films present enhanced volumetric capacitances (C_V) (Fig. 4f). The largest C_V (141.4 F cm^{-3}) was delivered by MoS₂/PEDOT-2 film at a current density of 0.2 A g^{-1} , much higher than that of neat MoS₂ (59.9 F cm^{-3}) and neat PEDOT:PSS (44.8 F cm^{-3}) films at the same current density. At a high current density of 4 A g^{-1} , MoS₂/PEDOT-2 film could still afford a capacitance of 94.3 F cm^{-3} , showing a capacitance retention ratio of 66.7%, whilst neat MoS₂ and PEDOT:PSS films display a lower retention ratio of 54.1% and 54.0%, respectively. This enhanced capacitive performance can be attributed to the incorporation of PEDOT:PSS between MoS₂ nanosheets, hence improving the conductivity and charge transfer.

The cycling performance of the film electrodes was investigated at a current density of 1 A g^{-1} . Both neat PEDOT:PSS and neat MoS₂ films showed a capacitance drop of over 10% in the first 2000 cycles (Fig. 4g). At the 5000th cycle, the former offered a capacitance retention rate of 85.0%, while the latter only retained 73.4% of its initial capacitance. In contrast, MoS₂/PEDOT-2 electrode only showed a slight volumetric capacitance loss over 5000 cycles. The retained capacitance was 116.2 F cm^{-3} , 98.6% of the initial capacitance (117.8 F cm^{-3}), suggesting its excellent cycling stability. Such cycling performance is superior to the reported MoS₂-conjugated polymer composite electrodes, such as 90% retention after 1000 cycles for MoS₂/PEDOT composites[25] or 85% after 4000 cycles for MoS₂/polypyrrole composites^[14]. It is also higher than the reported MoS₂/GO films (95% after 10000 cycles at 300 mV s^{-1}).^[18] These cells were disassembled for investigation. Compared to the pristine films, cracks were generated on the MoS₂ film after electrochemical cycling (Figure S2a, b), while the MoS₂/PEDOT-2 film still remained intact (Figure S2c, d). This clearly suggests improved mechanical integrity in the hybrid film, leading to good cycling stability.

The volumetric energy density and power density of the devices were calculated using the equations of $E=[C_V \times (\Delta V)^2]/(2 \times 4 \times 3600)$ and $P=(3600 \times E)/t$, where E is the volumetric energy density in Wh cm^{-3} , P is the volumetric power density in W cm^{-3} . The device based on $\text{MoS}_2/\text{PEDOT-2}$ films presented a volumetric energy density of 4.9 mWh cm^{-3} at a volumetric power density of 0.19 W cm^{-3} . At the highest discharge current density, $\text{MoS}_2/\text{PEDOT-2}$ could still deliver a volumetric power density of 3.9 W cm^{-3} with an energy density of 3.3

Wh cm^{-3} . The Ragone plot of the supercapacitors based on $\text{MoS}_2/\text{PEDOT-2}$ electrodes and the results from some recently reported MoS_2 -based supercapacitors are shown in Fig. 4h. The 1T- MoS_2 film displayed a superior energy density of up to 16 mWh cm^{-3} in aqueous electrolyte.[17] This may be ascribed to its high content of 1T- MoS_2 nanosheets ($\sim 70\%$) and the low thickness of the film, only $\sim 1 \text{ }\mu\text{m}$. It should be pointed out that the film thickness can dramatically influence the capacitive performance, since a higher ion diffusion length in the thick film leads to lower charge/discharge rates and power densities.[44] The thicknesses of our films are close to those of commercial cell electrodes, which are in the range of 10 to several hundreds of microns.[45, 46] The energy densities obtained using $\text{MoS}_2/\text{PEDOT}$ films are also higher than or comparable to that of MoS_2/GO composites[18] and directly deposited MoS_2 thin film[47], thermally reduced graphene oxide-based microsupercapacitors (TG MSCs)[48] or methane-plasma-treated graphene-based microsupercapacitors (MPG MSCs)[48]. These results are also higher than observed with conventional electrolytic capacitors[49] and lithium thin film batteries,[50] suggesting its potential applications as a practical supercapacitor electrode. We should also point out that our free-standing $\text{MoS}_2/\text{PEDOT}$ films possess better electrochemical performance and remarkably enhanced mechanical robustness and flexibility compared to those reported for $\text{MoS}_2/\text{graphene}$ films[18]

and graphene/polymer films[33, 34] suggesting that use in flexible energy storage devices is viable.

Nyquist plots of electrochemical impedance spectroscopy (EIS) for these film electrodes are depicted in Fig. 5a. The simulated equivalent circuit consists of four elements (inset of Fig. 5a): bulk resistance (R_s), charge-transfer resistance (R_{ct}), Warburg impedance (W) and constant phase element (CPE). The detailed values of each element are listed in **Table S1** (see supporting information). The hybrid films have a much smaller R_{ct} (50.6, 57.8 and 69.5 Ω for MoS₂/PEDOT-1, 2 and 5 respectively) than that of neat films (106.7 Ω). The linear parts at the low frequency region are related to the ion diffusion process. It can be seen that all the hybrid films displayed nearly vertical lines ($>80^\circ$ with Z' axis), indicating a nearly ideal capacitive behaviour.[51] In contrast, neat MoS₂ film displayed a $\sim 45^\circ$ linear part, indicating the high diffusion resistance of ions in the structure of the electrodes.[52] These results clearly demonstrate that these hybrid films can allow faster ion diffusion and charge transport, which leads to the greatly improved electrochemical properties (*e.g.* rate performance) as demonstrated.

To investigate the potential application of these hybrid films in flexible devices, the MoS₂/PEDOT-2 films were further assembled into all-solid-state supercapacitors. The device (inset of Fig. 5b) was tested at a scan rate of 50 mV s⁻¹ from 0 to 1 V under different bending angles (Fig. 5b). The volumetric capacitances of the single electrode were calculated using the equation: $C_V = \rho \times C_g = \frac{\rho}{mv\Delta V} \int I dV$, where, v is the scan rate in V s⁻¹, ΔV is the potential window in V and I is the current in A. At the relaxation (unbent) state, the MoS₂/PEDOT-2 films supercapacitor delivered a C_V of 156.3 F cm⁻³. When being bent to 90°, it displayed a well remained CV curve offering a capacitance of 150.9 F cm⁻³, and a high capacitance retention rate of 96.6%. Even upon a 180° bending, the hybrid film still delivered a C_V of

137.2 F cm⁻³, a retention rate of 87.8%. This device was subjected to a bending process for up to 1000 times at 90°, no significant changes can be observed (Fig. 5c). It could still deliver a volumetric capacitance of 125.1 F cm⁻³, 80.0% of that obtained from the initial unbent state. The robustness and durability are very important features for practical bendable/flexible supercapacitors. This proven integrity of these hybrid films against repeated bending indicates that they are promising electrodes for use as flexible supercapacitors.

4. Conclusions

Free-standing MoS₂/PEDOT hybrid films were developed by simply incorporating PEDOT:PSS into the chemically exfoliated MoS₂ nanosheets via a simple vacuum filtration technique. These hybrid films showed substantially enhanced mechanical properties compared to neat MoS₂ film, which can be explained by that the polymer PEDOT acted as glue between the MoS₂ nanosheets. The robustness and flexibility of these electrodes could also be evidenced by the electrode integrity being retained over 1000 bending cycles. The highly conductive and hydrophilic PEDOT:PSS also effectively improved the conductivity and charge delivery, resulting in greatly improved electrochemical properties. The MoS₂/PEDOT-2 hybrid film exhibited a large volumetric capacitance of 141.4 F cm⁻³, a capacitance retention ratio of 98.6% over 5000 cycles and a volumetric energy density of 4.9 mWh cm⁻³. The combination of good capacitive performance and mechanical properties suggests its promising use for high-performance flexible supercapacitors.

Figure captions

Fig. 1 AFM image (a) and height profile (b) along the line drawn in (a) of exfoliated MoS₂ nanosheets; (c) TEM image of MoS₂ nanosheets.

Fig. 2 Cross-sectional view (a-g) and strain-stress curves (h) of the films. (a) Neat PEDOT:PSS, (b) neat MoS₂, (c) MoS₂/PEDOT-1, (d) MoS₂/PEDOT-2 and (e) MoS₂/PEDOT-5 films. (f, g) Cross-section of MoS₂ and MoS₂/PEDOT-2 films at higher magnification. Inset of (f): a photo of a flexible MoS₂/PEDOT-2 film.

Fig. 3 (a) Raman spectra of bulk MoS₂ powder, MoS₂ film and MoS₂/PEDOT films. (b) XPS spectra of bulk MoS₂ powder, neat MoS₂ and MoS₂/PEDOT-2 film, showing the Mo 3d binding region.

Fig. 4 (a-c) Cyclic voltammograms of the supercapacitor composed of MoS₂/PEDOT-2 (a), and neat MoS₂ films (b) at different scan rates; comparison between these two supercapacitors and that with neat PEDOT:PSS films at a scan rate of 50 mV s⁻¹ (c) in 1 M Na₂SO₄. (d) Galvanostatic charge/discharge curves of MoS₂/PEDOT-2 film supercapacitor at different current densities. (e, f) Charge/discharge curves at a current density of 0.2 A g⁻¹ (e) and volumetric capacitances as a function of current densities (f) of the supercapacitors composed of these film electrodes. (g) Cycling stability of the supercapacitors based on neat MoS₂, neat PEDOT:PSS and MoS₂/PEDOT-2 film electrodes. (h) Ragone plot of volumetric power and energy densities reported from previously reported MoS₂-based energy storage materials and some commonly applied energy storage devices for comparison with MoS₂/PEDOT-2 film.

Fig. 5 (a) Nyquist plots (symbol) and the simulated curves (line) of neat and hybrid films based supercapacitors in 1 M Na₂SO₄ (inset: the equivalent circuit diagram used to simulate the Nyquist plots). (b) Cyclic voltammograms of MoS₂/PEDOT-2 film based supercapacitor

at different bending angles at a scan rate of 50 mV s^{-1} (inset: photo of the flexible supercapacitor device). (c) Cyclic voltammograms of $\text{MoS}_2/\text{PEDOT-2}$ recorded during the bending process.

Table 1 Mechanical properties and electrical conductivities of MoS_2 , PEDOT:PSS and $\text{MoS}_2/\text{PEDOT}$ hybrid films.

Types of Films	Fracture strength (MPa)	Young's modulus (GPa)	Max elongation (%)	Conductivity (S cm^{-1})
PEDOT:PSS	35.9	1.3	3.8	104.2
MoS_2	5.3	2.7	0.3	0.5
$\text{MoS}_2/\text{PEDOT-1}$	23.5	1.9	1.4	17.9
$\text{MoS}_2/\text{PEDOT-2}$	18.0	2.0	0.9	11.9
$\text{MoS}_2/\text{PEDOT-5}$	7.4	2.2	0.4	4.4
