Abstract

We obtain explicit formulae for the values of the $2v-j$ minors, $j = 0, 1, 2$ of $D$-optimal designs of order $2v = x^2 + y^2$, $v$ odd, where the design is constructed using two circulant or type 1 incidence matrices of either two SBIBD$(2s^2 + 2s + 1, s^2, \frac{2s^2 + 2s + 1}{s^2}, s(s - 1))$ or $2 - \{2s^2 + 2s + 1; s^2, s^2; s(s - 1)\}$ sds. This allows us to obtain information on the growth problem for families of matrices with moderate growth. Some of our theoretical formulae imply growth greater than $2(2s^2 + 2s + 1)$ but experimentation has not yet supported this result. An open problem remains to establish whether the $(1, -1)$ CP incidence matrices of certain SBIBDs and $2 - \{2s^2 + 2s + 1; s^2, s^2; s(s - 1)\}$ sds which yield $D$ optimal designs, can have growth greater than $2v$.

Key Words and Phrases: $D$-optimal designs, SBIBD, supplementary difference sets, Gaussian elimination, growth, complete pivoting.

AMS Subject Classification: 05B20, 15A15, 65F05, 65G05.

1 Introduction

A $D$-optimal design of order $n$ is an $n \times n$ matrix with entries $\pm 1$ having maximum determinant. In the present paper we evaluate the $2v-j$, $j = 0, 1, 2$ minors for $(1, -1)$ incidence matrices of certain SBIBDs which yield $D$-optimal designs. For the purpose of this paper we will define a SBIBD$(v, k, \lambda)$ to be a $v \times v$ matrix, $B$, with entries 0 or 1, which has exactly $k$ entries $+1$ and $v-k$ entries 0 in each row and column and for which the inner product of any distinct pairs of rows and columns is $\lambda$. The $(1, -1)$ incidence matrix of $B$ is obtained by letting $A = 2B - J$, where $J$ is the $v \times v$ matrix with entries all $+1$. We write $I$ for the identity matrix of order $v$. Then we have

$$BB^T = (k - \lambda)I + \lambda J \quad (1)$$

and

$$AA^T = 4(k - \lambda)I + (v - 4(k - \lambda))J \quad (2)$$

It can be easily shown that
\[
\det B = (k - \lambda)^{v-1} \sqrt{k + (v - 1)\lambda}
\]
and since \( \lambda(v - 1) = k^2 - k \)
\[
\det A = 2^{v-1} (k - \lambda)^{v-1} |v - 2k|
\]  
(3)

In this paper we also study the application of the computed values of the minors to the growth problem for SBIBD \((2s^2 + 2s + 1, s^2, \frac{1}{2}s(s - 1))\), which is Brouwer’s design and which yields a D-optimal design.

Let \( A = [a_{ij}] \in \mathbb{R}^{n \times n} \). We reduce \( A \) to upper triangular form by using Gaussian elimination with complete pivoting (GECP) [19]. Let \( A^{(k)} = [a_{ij}^{(k)}] \) denote the matrix obtained after the first \( k \) pivoting operations, so \( A^{(n-1)} \) is the final upper triangular matrix. A diagonal entry of that final matrix will be called a pivot. Matrices with the property that no exchanges are actually needed during GECP are called completely pivoted (CP). Let \( g(n, A) = \max_{i,j,k} |a_{ij}^{(k)}|/|a_{11}^{(0)}| \) denote the growth associated with GECP on \( A \) and \( g(n) = \sup \{ g(n, A) | A \in \mathbb{R}^{n \times n} \} \). The problem of determining \( g(n) \) for various values of \( n \) is called the growth problem.

The determination of \( g(n) \) remains one of the major unsolved problems in numerical analysis. See [9] for a detailed description of the problem. One of the curious frustrations of the growth problem is that it is quite difficult to construct any examples of \( n \times n \) matrices \( A \) other than Hadamard matrices for which \( g(n, A) \) is even close to \( n \). The equality \( g(n, A) = n \) has been proved for a certain class of \( n \times n \) Hadamard matrices [4]. It has also been observed that weighing matrices of order \( n \) can give \( g(n, A) = n - 1 \) [12]. In [11] the pivot structure of \((1, -1)\) incidence matrices of SBIBD \((v, k, \lambda)\) is studied. In the present paper we get values for the pivots of \( 2 - \{2s^2 + 2s + 1, s^2, s(s - 1)\} \) sds, and D-optimal designs made from them. Calculations have given moderate values of growth for D-optimal designs. An open problem concerning the possibility of finding \((1, -1)\) \( 2v \times 2v \) CP D-optimal designs having growth greater than \( 2v \) is posed.

**Notation 1.** Write \( A \) for a matrix of order \( n \) whose initial pivots are derived from matrices with CP structure. Write \( A(j) \) for the absolute value of the determinant of the \( j \times j \) principal submatrix in the upper left-hand corner of the matrix \( A \) and \( A[j] \) for the absolute value of the determinant of the \((n - j) \times (n - j)\) principal submatrix in the bottom right-hand corner of the matrix \( A \). Throughout this paper when we have used \( i \) pivots we then find all possible values of the \( A(n - i) \) minors. Hence, if any minor is CP it must have one of these values. The magnitude of the pivots appearing after the application of GE operations on a CP matrix \( W \) is given by
\[
p_j = W(j)/W(j - 1), \quad j = 1, 2, \ldots, n, \quad W(0) = 1.
\]  
(4)

In particular for a CP SBIBD \((v, k, \lambda)\), \( A \),
\[
p_v = A(v)/A(v - 1), \quad p_{v-1} = A(v - 1)/A(v - 2).
\]  
(5)

We use the notation \( M_j \) to denote the \( j \times j \) minor of \( A \).

For completeness we give the determinant simplification theorem in Appendix as we use it extensively in this paper.
2  $D$-optimal designs of order $2v \equiv 2 \,(mod\, 4)$ from $SBIBDs$

Let $d_n$ denote the maximum determinant of all $n \times n$ matrices with elements $\pm 1$. It follows from Hadamard’s inequality that $d_n \leq n^{\frac{n}{2}}$ and it is easily shown that equality can only hold if $n = 1$ or 2 or if $n \equiv 0 \,(mod\, 4)$. We shall here be concerned with the case $n \equiv 2 \,(mod\, 4), \, n \neq 2$. Ehlich [6], showed that

$$d_n \leq (2n - 2)(n - 2)^{\frac{n}{2} - 1}$$

and equality can hold only if $2n - 2 = x^2 + y^2$, where $x$ and $y$ are integers.

Recently two infinite series of $n \times n \,(n \equiv 2 \,(mod\, 4))$ matrices with elements $\pm 1$ and maximum determinant were discovered. The first series (Koukouvios-Koumas-Seberry-Singer or KKSS) [10], exists for $n = 2(q^2 + q + 1)$ where $q$ is a prime power. The second series (Whiteman-Brouwer or WB) [18], exists for $n = 2(2q^2 + 2q + 1)$ where $q$ is an odd prime power.

For the purpose of this paper we will define two supplementary difference sets $2 - \{v; k_1, k_2; \lambda\}$, abbreviated as sds, to be two circulant (or type 1) $v \times v$ matrices $B_1$ and $B_2$, with entries 0 or 1, which have exactly $k_i$ entries $+1$ and $v - k_i$ entries $0$, $i = 1, 2$ respectively, in each row and column and for which the inner product of any pair of rows is $\lambda$. The $(1, -1)$ incidence matrices of $B_i$, are obtained by letting $A_i = 2B_i - J, \, i = 1, 2$.

The family of $SBIBD(2s^2 + 2s + 1, s^2, \frac{1}{2}s(s-1), \lambda)$, for $s$ an odd prime power, has been found by Brouwer [3]. For $s = 2$, the $SBIBD(13,4,1)$ comes from the projective plane. The case for $s = 4$, the $SBIBD(41,16,6)$ is given by Bridges, Hall and Hayden [2] and independently by van Trung [16]. The case for $s = 6$, the $SBIBD(85,36,15)$ is given as unknown by van Trung [17, p.84] and Beth, Jungnickel and Lenz [1, p.625]. However, for $s = 6$ Gysin [8] gives the first $2 - \{85;36;36;30\}$ sds. For $s = 8$ Djokovic [5] gives the first $2 - \{145;64;64;56\}$ sds. Georgiou and Koukouvios [7] give further results for $s = 6$ and $s = 8$. In addition, for $s = 3$, i.e. $2 - \{25;9;9;6\}$, there is a type 1 solution in the group $Z_5 \times Z_5$.

These $2 - \{2s^2 + 2s + 1; s^2, s^2; s(s - 1)\}$ sds have $(1, -1)$ incidence matrices which satisfy

$$A_1A_1^T + A_2A_2^T = (4s^2 + 4s)I + 2J$$

Let $R$ and $S$ be permutation matrices of order $v$. Then $A$ given by

$$\begin{bmatrix} P & P \\ RPS & -RPS \end{bmatrix} \text{ or } \begin{bmatrix} A_1 & A_2 \\ A_2^T & -A_1^T \end{bmatrix}$$

are $D$-optimal designs of order $2v \equiv 2 \,(mod\, 4)$ of the WB family. We can say the WB family is constructed from $2 - \{2s^2 + 2s + 1; s^2, s^2; s(s - 1)\}$ sds. Note $A_1 = A_2$ for the WB family.

We can write

$$AA^T = (2v - 2)I_{2v} + 2I_2 \times J_v.$$ 

It is easy to use the determinant simplification theorem to see that

$$det \, A = 2^v (2v - 1)(v - 1)^{v-1}.$$
Since $A$ has been constructed using the $2 - \{2s^2 + 2s + 1; s^2, s^2, s(s - 1)\}$ sds,

$$\det A = M_{2v} = 2^{2(s+1)^2} (2s + 1)^2 (s + 1)^{2s(s+1)}.$$  (6)

### 2.1 Minors of Size $(2v - 1)$

To find the $(2v - 1) \times (2v - 1)$ minors we remove the first row and column of $A$ to get $B$. Now, $\det AA^T = \det \Delta(h, i, j, k, m)$ where

$$\Delta(h, i, j, k, m) = \begin{bmatrix}
    m & 1 & \cdots & 1 & 3 & 3 & \cdots & 3 & - & - & \cdots & - & 1 & 1 & \cdots & 1 \\
    1 & m & \cdots & 1 & 3 & 3 & \cdots & 3 & - & - & \cdots & - & 1 & 1 & \cdots & 1 \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
    1 & 1 & \cdots & m & 3 & 3 & \cdots & 3 & - & - & \cdots & - & 1 & 1 & \cdots & 1 \\
    3 & 3 & \cdots & 3 & m & 1 & \cdots & 1 & 1 & 1 & \cdots & 1 & - & - & \cdots & - \\
    3 & 3 & \cdots & 3 & 1 & m & \cdots & 1 & 1 & 1 & \cdots & 1 & - & - & \cdots & - \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
    1 & 1 & \cdots & 1 & - & - & \cdots & - & 1 & 1 & \cdots & 1 & m & 1 & \cdots & 1 \\
    1 & 1 & \cdots & 1 & - & - & \cdots & - & 3 & 3 & \cdots & 3 & 1 & m & \cdots & 1 \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
    1 & 1 & \cdots & 1 & - & - & \cdots & - & 3 & 3 & \cdots & 3 & 1 & m & \cdots & 1 \\
    \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots \\
    1 & 1 & \cdots & 1 & - & - & \cdots & - & 3 & 3 & \cdots & 3 & 1 & m & \cdots & 1 \\
    \end{bmatrix}$$  

$m = h + i + j + k$. Then by the determinant simplification theorem

$$\det \Delta(h, i, j, k, m) = (m - 1)^{m-4} \begin{vmatrix}
    m - 1 + h & 3h & -h & h \\
    3i & m - 1 + i & i & -i \\
    -j & j & m - 1 + j & 3j \\
    k & -k & 3k & m - 1 + k \\
    \end{vmatrix}$$

and $\det \Delta(h, i, j, k, m) = (m - 1)^{4} + (m - 1)^3(i + j + h + k) - 8(m - 1)^2(jk + ih) - 16(m - 1)(jk(i + h) + ih(j + k))$. Now $\det BB^T$ is obtained from $\Delta(h, i, j, k, m)$ by removing a row and the corresponding column. Thus $\det BB^T$ is $\Delta(h - 1, i, j, k, m - 1)$ or $\Delta(h, i - 1, j, k, m - 1)$ or $\Delta(h, i, j - 1, k, m - 1)$ or $\Delta(h, i, j, k - 1, m - 1)$.

**Lemma 1** The $(2v - 1) \times (2v - 1)$ minors of the $D$-optimal designs of the WB series are

$$M_{2v-1} = 2^{4s(s+1)} (2s + 1)^{s^2 + 2s - 1} (s + 1)^{2s^2 + 2s}$$ and $$2^{s(s+1)} (2s + 1)^{s^2 + 2s} (s + 1)^{2s^2 + 2s - 1}$$

where $s$ is an odd prime power, $s = 2, 4, 6$ or 8.
Proof. Here we use the $(1, -1)$ incidence matrices of the $2 - \{2s^2 + 2s + 1; s^2, s^2, s(s - 1)\}$ sds. By the reasoning above, with $v = 2s^2 + 2s + 1$, $h = j = s^2$, $i = k = s^2 + 2s + 1$, $m = 4s^2 + 4s + 2$, substituted into $\Delta(h - 1, i, j, k, m - 1) = \Delta(h, i, j - 1, k, m - 1)$, we obtain the result. Specifically the determinant is the square root of the determinant given by

$$
\begin{vmatrix}
5s^2 + 4s - 1 & 3s^2 - 3 & -s^2 + 1 & s^2 - 1 \\
3s^2 + 6s + 3 & 5s^2 + 6s + 1 & s^2 + 2s + 1 & -s^2 - 2s - 1 \\
s^2 & s^2 & 5s^2 + 4s & 3s^2 \\
-2s + 1 & -s^2 - 2s - 1 & 3s^2 + 6s + 3 & 5s^2 + 6s + 1
\end{vmatrix}
$$

$$= 2^{2(4s^2 + 4s)}(s^2 + s)^{4s^2 + 4s - 2}(s + 1)^2(2s + 1)^2 = \left[2^{4s^2 + 4s}s^{2s^2 + 2s - 1}(s + 1)^2s^2 + 2s - 1(2s + 1)^2\right]^2$$

det $\Delta(h, i - 1, j, k, m - 1) = \det \Delta(h, i, j - 1, k, m - 1) = \left[2^{4s^2 + 4s}s^{2s^2 + 2s - 1}(s + 1)^2s^2 + 2s - 1(2s + 1)^2\right]^2$

gives the second result.

\[\Box\]

2.2 Minors of size $(2v - 2)$

As the partitioned matrix $A$ of the $D$-optimal design is composed from $2 - \{\{v; k_1, k_2; \lambda\}$ supplementary difference sets, these are in fact $2 - \{2s^2 + 2s + 1; s^2, s^2, s^2 - s\}$ sds. We will use $k = k_1 = k_2$ for all our calculations. Using the formula for the inner product of the rows of the $(1, -1)$ incidence matrix formed from these sds we see that the inner product is $2v - 4(k_1 + k_2 - \lambda) = 2$.

We now return to $A$ with two rows and columns removed to find the generic matrix. We have not included this in expanded form except for one case but moved straight to the determinant after it has been simplified using the Determinant Simplification Theorem, of the matrix $D$ given by

$$
\begin{bmatrix}
2v - 2 & 2u_2 & 2u_3 & 4u_4 & -2u_5 & 0 & 0 & 2u_8 \\
2u_1 & 2v - 2 & 4u_3 & 2u_4 & 0 & -2u_6 & 2u_7 & 0 \\
2u_1 & 4u_2 & 2v - 2 & 2u_4 & 0 & 2u_6 & -2u_7 & 0 \\
4u_1 & 2u_2 & 2u_3 & 2v - 2 & 2u_5 & 0 & 0 & -2u_8 \\
-2u_1 & 0 & 0 & 2u_4 & 2v - 2 & 2u_6 & 2u_7 & 4u_8 \\
0 & -2u_2 & 2u_3 & 0 & 2u_5 & 2v - 2 & 4u_7 & 2u_8 \\
0 & 2u_2 & -2u_3 & 0 & 2u_5 & 4u_6 & 2v - 2 & 2u_8 \\
2u_1 & 0 & 0 & -2u_4 & 4u_5 & 2u_6 & 2u_7 & 2v - 2
\end{bmatrix}
$$

This gives the determinant of $A$ with two rows and columns removed, as $(4s^2 + 4s)^{2s^2 + 2s - 1}\sqrt{\det D}$.

To calculate the minors of size $(2v - 2)$ we distinguish two major Cases: Case I where the two rows removed to form the minor came from the same part of the $D$-optimal design that is they have inner product 2; Case II where the two rows removed to form the minor came from different parts of the $D$-optimal design that is they have inner product zero. This leads to the following four subcases:
Case Ia \[
\begin{bmatrix}
  x & y \\
  y & \bar{y}
\end{bmatrix}
\] where the (1,1) and (2,1) elements have the same sign, the (1,2) element and the (2,2) element have opposite signs, and the inner product of row one and two with each other is 2. The inner product of the first two rows with the next \(|v-i|\) rows is \(+i\) and the inner product of row one and two with the \(v+3-i\) to \(2v\) rows is \(2-i\), where \(i = 2\) or 0.

Case Ib \[
\begin{bmatrix}
  x & y \\
  y & \bar{y}
\end{bmatrix}
\] where the (1,1) and (2,1) elements have the same sign, the (1,2) element and the (2,2) element have opposite signs, and the inner product of rows one and two with each other is +2. The inner product of rows one and two with next \(v-i\) rows is \(+i\) and the inner product of the first two rows with rows \(v+3-i\) to \(2v\) is \(2-i\), where \(i = 2\) or 0.

Case IIa \[
\begin{bmatrix}
  x & y \\
  y & \bar{y}
\end{bmatrix}
\] where the (1,1) element and the (2,1) element have the same signs, the (1,2) element and the (2,2) element have different signs, and the inner product of rows one and two with each other is zero. Rows 3 to \(v+1\) have inner product +2 with row one and zero with row two. Rows \(v+2\) to \(2v\) have inner product zero with row one and +2 with row two.

Case IIb \[
\begin{bmatrix}
  x & y \\
  y & \bar{y}
\end{bmatrix}
\] where the (1,1) element and the (2,1) element have the same signs, the (1,2) element and the (2,2) element also have the same sign, and the inner product of row one and two with each other is zero. Rows 3 to \(v+1\) have inner product +2 with row one and zero with row two. Rows \(v+2\) to \(2v\) have inner product zero with row one and +2 with row two.

A careful study of cases leads to only the cases now listed as Case III not being permutation equivalent to one of Cases I and II.

Case III \[
\begin{bmatrix}
  x & y \\
  y & \bar{y}
\end{bmatrix}
\] where one of the columns in the submatrix has two identical elements and the other has two different elements. The inner product of rows one and two with each other is zero. Each of row one and row two have inner product \(i\) with \(v-1\) other rows and \(2-i\) with the remainder of the rows, \(i = 2\) or 0.

Case Ia
We have the possible \(2 \times 2\) submatrices:

\[
\begin{array}{cccccccc}
(i) & (ii) & (iii) & (iv) & (v) & (vi) & (vii) & (viii) \\
1 & y & y & 1 & y & 1 & \bar{y} & \bar{y} & 1 & \bar{y} & 1 & \bar{y} & 1 & y \\
1 & \bar{y} & \bar{y} & 1 & \bar{y} & 1 & y & y & 1 & y & 1 & y & 1 & y \\
\end{array}
\]

Since permutation of columns 1 and 2 has no effect on \(M_{2n-2}\) cases (i) and (iii), (v) and (vii), (ii) and (iv), and (vi) and (viii) give the same values. Cases (i) and (v) give the same values depending on whether \(y = 1\) or \(-1\) and similarly for cases (ii) and (vi). This leaves the following submatrices for Case Ia:
(i) \( y \)  
(ii) \( y' \)

\[ 1 \quad y \quad - \quad y \]
\[ 1 \quad y' \quad - \quad y' \]

However, in Cases I rows 1 and 2 may be permuted without altering the value of \( M_{2v-2} \), so, without loss of generality we may consider \( y = 1 \). Also, without loss of generality, we may permute rows three to \( 2v \) of the matrix so rows three to \( v \) have inner product \(+2\) with rows one and two. The inner product of rows one and two with the next \( v - 2 \) rows is 2, and the inner product of rows 1 and 2 with rows \( v + 1 \) to \( 2v \) is zero. This yields the following cases for Case Ia:

<table>

Case Ib

A similar argument to that for Case Ia shows that using the permutations of columns 1 and 2 we only have to consider the submatrices

(i) \( y \)  
(ii) \(-y\)  

for \( y = 1 \) and \( y = -1 \). We make the inner product with rows three to \( v \) with the first two rows equal +2 and the product of rows \( v + 1 \) to \( 2v \) with the first two rows equal 0.

\[
\begin{array}{c|cccccccc}
\text{2 x 2 submatrix} & w_1 & w_2 & w_3 & w_4 & w_5 & w_6 & w_7 & w_8 \\
\hline
1 & \lambda - 2 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
1 & \lambda - \lambda & \lambda - 2 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
1 & \lambda - \lambda & \lambda - \lambda & \lambda - 2 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
1 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
\end{array}
\]

Table 2

These reduce to three cases to test as the cases for \(-1\) and \(1\) give permutations, only of the terms to be evaluated.

Case IIa
A similar argument to that for Case Ia shows that using the permutations of columns one and two we only have to consider the submatrices

(i) \( y \)  
(ii) \(-y\)  

for \( y = 1 \) and \( y = -1 \). These give the results for Table 3.

\[
\begin{array}{c|cccccccc}
\text{2 x 2 submatrix} & w_1 & w_2 & w_3 & w_4 & w_5 & w_6 & w_7 & w_8 \\
\hline
1 & \lambda - 1 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
1 & \lambda - \lambda & \lambda - \lambda & \lambda - 1 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
1 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
1 & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda & \lambda - \lambda \\
\end{array}
\]

Table 3

These reduce to three cases to test as the cases for \(-1\) and \(1\) give permutations, only of the terms to be evaluated.

Case IIb
A similar argument to that for Case Ia shows that using the permutations of columns 1 and 2 we only have to consider the submatrices

(i) \( y \)  
(ii) \(-y\)  

for \( y = 1 \) and \( y = -1 \). These give the results for Table of IIb.
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline
\text{2 \times 2 submatrix} & \text{\(u_1\)} & \text{\(u_2\)} & \text{\(u_3\)} & \text{\(u_4\)} & \text{\(u_5\)} & \text{\(u_6\)} & \text{\(u_7\)} & \text{\(u_8\)} \\
\hline
1 & 1 & \lambda - 1 & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda \\
-1 & 1 & \lambda & \xi - \lambda & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda & \xi - \lambda & \nu - 2k + \lambda \\
1 & -1 & \lambda & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda \\
-1 & -1 & \lambda & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda - 1 & \xi - \lambda & \xi - \lambda & \nu - 2k + \lambda - 1 \\
\hline
\end{tabular}

Table 4

These reduce to three cases to test as the cases for \(-1\) and \(1\) give permutations, only of the terms to be evaluated.

**Case III**

We have the following 2 \times 2 submatrices.

(i) \hspace{1cm} (ii)

\[
\begin{pmatrix}
 x & y \\
 y & x \\
\end{pmatrix}
\hspace{1cm}
\begin{pmatrix}
 x & \overline{y} \\
 \overline{y} & x \\
\end{pmatrix}
\]

One column removed comes from the columns with \(2k\) ones per column and the other from the columns with \(v\) ones per column in the original design. This means the generic form of these two columns is

\[
\begin{pmatrix}
 1 & 1 \\
 1 & \rho \\
 1 & 1 \\
 1 & k \\
 \vdots & \vdots \\
 1 & k - \rho \\
 \vdots & \vdots \\
 1 & 1 \\
 \vdots & \vdots \\
 1 & v - k \\
 \vdots & \vdots \\
 1 & v - 2k + \rho \\
 \vdots & \vdots \\
 1 & 1 \\
 \vdots & \vdots \\
 1 & v - k \\
 \vdots & \vdots \\
 v - 2k + \rho \\
 \vdots & \vdots \\
 1 & 1 \\
 \vdots & \vdots \\
 1 & k - \rho \\
 \vdots & \vdots \\
 1 & \rho \\
 \vdots & \vdots \\
 1 & k - \rho \\
 \vdots & \vdots \\
 1 & \rho \\
 \vdots & \vdots \\
 1 & k - \rho \\
 \end{pmatrix}
\]

Note they have inner product zero. Also note \(0 \leq \rho \leq k\). We have not proceeded to eliminate cases for \(\rho\) except where \(\rho - 1 < 0\). The table lists the possible cases that arise. In the case of
1 − 1 − − the u_i, i = 1, . . . , 8 were permutations of each other. This also occurred for
1 − 1 − − 1 and for 1 1 1 1 − . So we have five theoretical values for Case III.

Table 5

**Lemma 2** The (2v − 2) × (2v − 2) minors of the D-optimal design of the WB series are

\[(2s + 1)(s + 1)sT, \quad (2s + 1)s^2T, \quad 2s^2(s + 1)T, \quad s(2s^2 + 2s + 1)T, \quad 2s(s + 1)^2T, \quad 2s^3T\]

where s is an odd prime power, s = 2, 4, 6 or 8 and T = \(2^{4s^2 + 4s - 1} s^{2s^2 + 2s - 3}(s + 1)^{2s^2 + 2s - 2}\).

**Proof.** Here \(λ = \frac{1}{2}(s - 1), \quad k = s^2, \quad v = 2s^2 + 2s + 1\). The expressions for u_i, i = 1, . . . , 8 were calculated in each case. Maple was then used to evaluate the determinant for D giving the required result. Ia and IIa give the values \(2^7 s^3(2s + 1)(s + 1)^3\) and \(2^7 s^3(2s + 1)(s + 1)^2\).

Cases Ib and IIb give the value zero for the determinant. Case III give the values \(2^7 s^3(2s + 1)^3, \quad 2^7(2s^3 + 2s + 1)(s + 1)^2 s^2, \quad 2^8 s^2(s + 1)^4\) and \(2^8 s^4(s + 1)^2\). Multiplying by \(4s^2 + 4s\) gives the required result. □

3 Pivot structure for WB family of D–optimal designs

**Conjecture (The growth conjecture for WB family)**

Let A be an 2v × 2v CP D-optimal design of WB family which is constructed from \(2 − (2s^2 + 2s + 1; s^2, s^2; s(s − 1))\) sds. Reduce A by GE. Then we conjecture

(i) \(g(v, A) = 2s(2s + 1), \quad \text{or} \quad 2(s + 1)(2s + 1)\);

(ii) The last pivot is equal to \(2s(2s + 1)\) or \(2(s + 1)(2s + 1)\);

(iii) The second last pivot can take the values \(2s(s + 1) = \frac{2s + 1}{2}, 2s^2, 2(s + 1)^2, (s + 1)(2s + 1), \quad \frac{(2s + 1)(2s + 1)^2}{(2s^2 + 2s + 1)}, s(2s + 1), \quad \frac{(s + 1)^2(2s + 1)}{s}, \quad \frac{(s + 1)^2(2s + 1)}{(s + 1)}\) and \(\frac{(2s + 1)(2s^2 + s + 1)}{(2s^2 + 2s + 1)}\);

(iv) Every pivot before the last has magnitude at most \(2v\);

(v) The first four pivots are equal to 1, 1, 2, 2, 4;

(vi) The fifth pivot may be 2 or 3.
We prove (ii) and (iii) in this paper. (v) and (vi) were proved for Brouwer’s SBIBD \((2s^2 + 2s + 1, s^2, 1, s(s - 1))\) in [11] and we also show they hold for the WB family.

**Theorem 1** Let \(A\) be the \(2v \times 2v\) D-optimal design of the WB family. Reduce \(A\) by GECP. Then the last pivots are \(2s(2s + 1)\) and \(2(s + 1)(2s + 1)\). The second last pivots are \(2s(s + 1), 2s^2, (s + 1)(2s + 1), \frac{(2s + 1)2s(s + 1)^2}{(2s^2 + 2s + 1)}\), \(s(2s + 1), \frac{(s + 1)^2(2s + 1)}{s}, \frac{(s^2(2s + 1))}{s(s + 1)}\), and \(\frac{(2s + 1)2s^2}{(2s^2 + 2s + 1)}\)

**Proof.** From (4) and lemma’s 1 and 2 we have for the D-optimal design made using \(2 - \{2s^2 + 2s + 1, s^2, s^2; s(s - 1)\}\) sds, the results in Table 6 where the first row gives the values of \(M_{2v-1}\), the first column gives the values of \(M_{2v-2}\) and the entries are \(p_{2v} = \frac{M_{2v-1}}{M_{2v-2}}\).

</tbody>
</table>

Table 7 (continued)

**Remark 1** We experimented with \(2v = 26\). The theoretical values for \(M_{2v-1}\) are \(2^{35} \cdot 5 \cdot 3^{12}\) and \(2^{36} \cdot 5 \cdot 3^{11}\). In our calculations we found always \(p_{2v} = 20\) and \(p_{2v-1} = 12\) or 10 or \(\frac{180}{1}\). This leaves as an open problem the existence of a \(26 \times 26\) matrix having growth equal to 30. □
The next result is easy to prove using a counting argument and noting the inner product of every pair of rows is +1 to see that the design always contains a $4 \times 4$ Hadamard matrix.

**Proposition 1** Let $A$ be the $2v \times 2v$ $(1, -1)$ incidence matrix of an SBIBD of the WB family. Reduce $A$ by GECP then the magnitudes of the first four pivots are 1, 2, 2 and 4; the magnitude of $|a_{55}^{(4)}|$ is 2 or 3.

**Proof:** Since the design always contains a $4 \times 4$ Hadamard matrix, this can be moved to be the $4 \times 4$ principal minor without changing the CP property. Thus the first four pivots will be 1, 2, 2 and 4 [4]. Because every entry in $A^{(3)}$ is of magnitude 0, 2 or 4, pivoting on $a_{44}$ will only involve adding ±1 or ±1/2 times the fourth row of $A^{(3)}$ to the rows below, and this will create only integer entries in $A^{(4)}$. It is known, see Payne [14], that if $v \equiv 1 \mod(4), \space v \neq 1$, $d_v \leq (v-1)^{2v-1}/2v-1$ and equality can hold only if $v = 2s^2 + 2s + 1, \space s = 1, 2, 3, \ldots$. Thus $|a_{55}^{(4)}|$ must be an integer satisfying the relation

$$A(1 \ 2 \ 3 \ 4 \ 5) = 16|a_{55}^{(4)}| \leq 4^{v/2} \sqrt{10-1} \Rightarrow |a_{55}^{(4)}| \leq 3.$$ 

where $A(1 \ 2 \ 3 \ 4 \ 5)$ denotes the determinant of the $5 \times 5$ principal submatrix of $A$. Thus $|a_{55}^{(4)}|$ must be 1, 2 or 3. To see that it cannot be 1 is to show that one could not have

$$A^{(4)} = \begin{bmatrix}
1 & 2 & 2 & 4 \\
2 & 2 & \ & \\
4 & \ & \\
B & & & \end{bmatrix}$$

where every entry of $B$ is zero or ±1; for, if that were true, then $B$ would be a normalized $(v-4) \times (v-4)$ matrix, and so

$$|\det(B) \leq (v-4)^{v-4}/16.$$ 

But $|\det(B) = 16^{-1/2}(v-1)^{v-1}/2v-1$ and it is easily checked that these cannot both hold when $v > 4$. $\square$

By detecting the pivot structure of WB, Table 8 was computed. The first nine pivots and the last two are presented. All the other intermediate pivots take a variety of values. At least 837 different pivot structures were detected for $2v = 26$ and 500 for $2v = 50$.

Table 8: Growth Factors and Pivots Patterns for small CP WB designs
References

4 Appendix A: The Determinant Simplification Theorem

We use the notation

\[ C \Sigma T = (k - a_{ii})J_{b_1, b_2, \ldots, b_s} + a_{ij}J_{b_1, b_2, \ldots, b_s} \]

for a matrix of blocks with integer multiples. For example the matrix

\[
C \Sigma T = (k - a_{ii})J_{u, v, w, x} + a_{ij}J_{u, v, w, x}
\]

where \((a_{ij})\) is the \((u + v + w + x) \times (u + v + w + x)\) matrix

\[
\begin{bmatrix}
    a & b & c & d & e & f & g & h \\
    b & a & e & f & c & e & a & g \\
    c & e & a & g & d & f & a & d \\
    d & f & a & d & g & e & f & a \\
\end{bmatrix}
\]

We now give a theorem proved similarly to the proof for finding the determinant of an SBIBD in [15, Theorem 3,p.32].

**Theorem 2 (Determinant Simplification Theorem)** Let

\[ C \Sigma T = (k - a_{ii})J_{b_1, b_2, \ldots, b_s} + a_{ij}J_{b_1, b_2, \ldots, b_s} \]

then

\[
det C \Sigma T = \prod_{i=1}^{s} (k - a_{ii})^{b_i - 1} det D
\]

where

\[
D = \begin{bmatrix}
    k + (b_1 - 1)a_{11} & b_2 a_{12} & b_3 a_{13} & \cdots & b_s a_{1s} \\
    b_1 a_{21} & k + (b_2 - 1)a_{22} & b_3 a_{23} & \cdots & b_s a_{2s} \\
    \vdots & \vdots & \ddots & \ddots & \vdots \\
    b_1 a_{s1} & b_2 a_{s2} & b_3 a_{s3} & \cdots & k + (b_s - 1)a_{ss}
\end{bmatrix}
\]
Corollary 1 Suppose $C$ is the matrix of order $(u + v + w + x) \times (u + v + w + x)$, where $n = u + v + w + x$, for which $CC^T$ is given above, satisfying $CC^T = (k - a_i)I_{u,v,w,x} + a_ijI_{u,v,w,x}$. Then

$$det \ CC^T = (k - a)^{n-4} det \ D$$

where

$$D = \begin{bmatrix}
    k + (u - 1)a & vb & wc & xd \\
    ub & k + (v - 1)a & we & xf \\
    uc & ve & k + (w - 1)a & xg \\
    ud & vf & wg & k + (x - 1)a
\end{bmatrix}.$$ 

(9)
