A semi-analytic valuation of American options under a two-state regime-switching economy

Abstract

In this study, we develop a semi-analytic method to evaluate American options under a two-state regime-switching economy. The two free boundaries corresponding to the states divide the pricing domain into two regions: a common continuation region and a transition region. Non-linear partial differential equation (PDE) systems are derived under the Black-Scholes framework for each region. The Laplace transform method is used to solve the PDE systems. Equations for determining the optimal exercise prices are obtained analytically and solved numerically in the Laplace space. A numerical inversion technique is then used to obtain the free boundaries and the option prices in the original time space. The results of various examples show that our technique is efficient and accurate.

Abstract

In this study, we develop a semi-analytic method to evaluate American options under a two-state regime-switching economy. The two free boundaries corresponding to the states divide the pricing domain into two regions: a common continuation region and a transition region. Non-linear partial differential equation (PDE) systems are derived under the Black-Scholes framework for each region. The Laplace transform method is used to solve the PDE systems. Equations for determining the optimal exercise prices are obtained analytically and solved numerically in the Laplace space. A numerical inversion technique is then used to obtain the free boundaries and the option prices in the original time space. The results of various examples show that our technique is efficient and accurate.

Keywords: American options, Regime-switching, Semi-analytic solution, Laplace transform

1 Introduction

The classical Black-Scholes model for option pricing assumes constant volatility. However, the volatility, which represents the risk of stock returns [18] and the economic condition [7], does change over time in financial markets [34–36]. In addition, the presence of a volatility smile (or skew) and a volatility term structure shows that the classical Black-Scholes model does not fully reflect market dynamics [27]. Thus, there is a practical need to search for models that better capture market dynamics.

There are various studies in the literature, which aim to provide more realistic reflection of financial markets. The models can be mainly categorized into the following: the volatility being treated as an unknown process, local volatility, stochastic volatility models, and regime-switching models. The approach by letting volatility as an unknown process was proposed by Avellaneda et al. [2]. The introduction of this unknown volatility, however, can lead to an extra non-linearity

*Corresponding author, xplu@uow.edu.au

to the PDE which increases the difficulty in the solution process as pointed out in [3]. Local volatility as a deterministic function of stock price and time is proposed by Dupire, Derman and Kani [15, 16]. This volatility model has been widely used in industry for its fast calibration [17]. However, the model needs continuous and smooth implied volatility surface, and numerical method applied for local volatility can be unstable. Some studies also pointed out that the performance of local volatility model is not satisfying since it is too restrictive [8, 32].

The stochastic model is considered to be more realistic [1]. Pricing models of a European option with stochastic volatility are used extensively in the literature, such as [4, 13, 33, 39]. Hull and White [26] proposed a model which used a log-normal distribution in their study. Stein and Stein [38] proposed the use of Ornstein-Uhlenbeck process in the pricing process. An analytical solution of European option with stochastic volatility in integral form is found by Heston [23]. Extension studies to deal with the integral form of Heston's solution is proposed by Zhu and Chen [48] and Zhyl'yevskyy [50]. However, numerical or approximation methods are still preferred over the more complicated closed form solutions due to the difficulties in numerical calculation in the Heston form solutions [12, 28].

Recently, regime-switching models have drawn much attention for option valuation [14, 20, 21, 25, 41, 43, 44]. In a regime-switching model, a key parameter of an asset, volatility, is driven by the market regime. In reality, the market change is driven by economic changes, investor's mood, business cycle expansion, etc. which often shows cyclic patterns [5]. The market regime switches among a finite number of states which represent the financial market conditions. A good agreement between a regime-switching model and empirical data in modeling the economic changes is reported in the study by Hardy [22]. Furthermore, the regime-switching models are less computation-intensive compared to the stochastic volatility models [25, 45].

While European options with regime-switching have been solved analytically in [11, 30, 31, 47], there is no analytical solution for the American counterpart due to the presence of the free-boundaries, except for perpetual options as presented by Guo in [20]. Numerical and analytical approximation methods have been developed as alternatives since the analytic solution for the American options with regime-switching is extremely difficult or even impossible to obtain. Numerical methods to value American options with regime-switching include, among others, the penalty method [29], finite element method [24, 40], and tree method [44]. To the best of the authors' knowledge, the only analytical approximation method available in the literature is the valuation of American options with regime-switching in finite maturity by Buffington and Elliott [10]. Their valuation is based on risk-neutral pricing, and an extension of the quadratic approximation of Barone-Adesi-Whaley [6]. The price of an American option with regime switching is decomposed into a European option part and an extra part as a result of American style privilege. While it is great for showing the American-style effect, the implementation of the method in [10] is not straight-forward. One should first calculate the European option value with regime switching, the calculation of which is not simple because although the solution is in closed form, it is in double integral form as the result of the discounted expectation (see the detail in [10, 19]). In

addition, there are two non-linear coupled equations for the optimal exercise prices to be solved numerically before the values of the option can be calculated.

In this work, we develop a semi-analytical method for the pricing of American options in a two-state regime-switching economy under the Black-Scholes framework. We aim to provide a method which is both efficient and accurate. Our method is based on the semi-analytic method in Zhu [46], where a pseudo-steady state approximation in Laplace space is used to tackle the free boundary in finite maturity American option problems. We follow Buffington and Elliott [10] and Guo [20, 21] in constructing the pricing domain for setting up the coupled partial differential equations for the different states. The equations for calculating the optimal exercise prices and option values are obtained in Laplace space analytically. The optimal boundaries are solved numerically in the Laplace space, then the results are inverted back to the original time space by the Stehfest method [37]. Although we cannot compare our results directly with those in [10] due to that fact that their numerical results are unavailable, we believe that our method should be more efficient judging by both solution processes and our computation times. As mentioned above the value of the American option in [10] is based on its European counterpart so in terms of computation one goes through the processes of calculating the European prices which involve double integrals and then the extra part due to American-style exercise right. In principal, our method without the need of evaluating double integrals would enhance computational efficiency. Our easy to implement approach coupled with its well balanced efficiency and accuracy makes it more advantageous and useful for practical applications.

The rest of the paper is organized as follows. Section 2 presents the formulation of the partial differential equation (PDE) systems for the pricing of American options under a regime-switching economy. Section 3 discusses the solution procedures of the PDE systems. Numerical examples are presented in Section 4 to show the accuracy and efficiency of the proposed method. Concluding remarks are given in Section 5.

2 Formulation of the PDE system

In a regime-switching economy, volatility, a key parameter of an asset is driven by market regimes which switch among a finite number of states representing the changes in financial markets. The stock price dynamics follows the SDE:

$$dS_t = (\mu - \delta)S_t dt + \sigma_{\bar{\varepsilon}(t)}S_t dW_t \quad (2.1)$$

where S_t is the underlying asset, μ is the drift, δ is a continuous dividend paid, $\bar{\varepsilon}(t)$ is a stochastic process representing the state of the economic cycle, and W_t is a Wiener process independent of $\bar{\varepsilon}(t)$.

It is assumed that $\bar{\varepsilon}(t)$ has finite state space $i, j \in I$ where $i \neq j$ and satisfies the Markov property. The volatility $\sigma_{\bar{\varepsilon}(t)}$ now is a stochastic process and has a different value for different

states $\bar{\varepsilon}(t)$. In this work, we assume that there are two regimes in the market representing two basic economic cycles

$$\bar{\varepsilon}(t) = \begin{cases} 1, & \text{the economy in a state of growth} \\ 2, & \text{the economy in a state of recession} \end{cases} \quad (2.2)$$

The transition between states occurs as a Poisson process and is defined as follows,

$$P(N(t + \tau) - N(t) = N(\tau) = k) = \frac{(\lambda_{ij}\tau)^k e^{-\lambda_{ij}\tau}}{k!}, \{i, j = 1, 2, i \neq j\}, \{k = 0, 1, 2, \dots\}$$

where $\lambda_{ij} > 0$ is the rate of the jump from state i to state j , and k is the number of occurrences of the jump within the time interval τ .

The presence of a regime-switching implies that the market is incomplete and the risk associated with the regime-switching cannot be uniquely determined and inseparable. Naik [31] shows that separable risk can be easily turned into inseparable one by adjusting the rate parameter of the switching process, without a loss of generality. Therefore, in this paper we assume that the risk is separable and not priced as in the works by Zhu et. al [47], Naik [31], Boyle [9] and Yi [42]. Furthermore, we assume the risk-free interest rate r remains constant.

Let the value of an American option when the economy is in the state of growth ($\bar{\varepsilon}(t) = 1$) be V_1 with volatility σ_1 . Then V_2 represents the value of the option when the economy condition is in a state of recession ($\bar{\varepsilon}(t) = 2$) with volatility σ_2 . We construct a portfolio by purchasing an option V and short Δ amount of underlying asset S ,

$$\Pi = V - \Delta S.$$

Consider at a time t when $\bar{\varepsilon}(t) = 1$, the value of the option would be $V_1(S, t)$. After a short time interval dt , the change in the portfolio is $d\Pi = dV - \Delta dS$. However, $dV = dV_1$ with the probability of $1 - \lambda_{12}dt$, and $dV = V_2 - V_1 + dV_2$ with the probability of $\lambda_{12}dt$. Under risk-neutral valuation, the investor is expected to make as much profit from the portfolio as they would from a risk-free investment, that is, $\mathbb{E}[d\Pi] = r\Pi dt$, where r is the risk-free interest rate. Using Ito's lemma and equation (2.1), the following pricing PDE for $V_1(S, t)$ can be derived (cf. [10], [47])

$$\frac{\partial V_1}{\partial t} + \frac{1}{2}\sigma_1^2 S^2 \frac{\partial^2 V_1}{\partial S^2} + (r - \delta)S \frac{\partial V_1}{\partial S} - rV_1 = \lambda_{12}(V_1 - V_2).$$

Similarly the PDE for $V_2(S, t)$ is derived as

$$\frac{\partial V_2}{\partial t} + \frac{1}{2}\sigma_2^2 S^2 \frac{\partial^2 V_2}{\partial S^2} + (r - \delta)S \frac{\partial V_2}{\partial S} - rV_2 = \lambda_{21}(V_2 - V_1).$$

In the following, the formulation of American calls under a regime-switching economy is presented. The formulation for American puts with regime-switching can be carried out in the

same way, or the values could be recovered from the put-call symmetry for American options [40]:

$$\begin{aligned} S_{f_i}^P(t; r; \delta) S_{f_i}^C(t; \delta; r) &= K^2, 0 \leq t \leq T \\ P_i(S, t; r; \delta) &= \frac{S}{K} C_i(K^2/S, t; \delta; r), 0 \leq t \leq T, 0 < S \end{aligned} \quad (2.3)$$

where K is the strike price, T the expiry date, P_i and C_i are the put and call prices, S_{f_i} stands for the optimal exercise price, and $S_{f_i}^k$ ($k = P, C$) optimal exercise price for put or call, respectively, corresponding to the economy states $i = 1, 2$.

American options under a two-state regime-switching economy have two optimal exercise boundaries, S_{f1} and S_{f2} corresponding to σ_1 and σ_2 , respectively. On the assumption in Equation (2.2), $\sigma_2 < \sigma_1$ so $S_{f2} < S_{f1}$ for American calls. The optimal boundaries S_{f1} and S_{f2} divide the pricing domain into two regions: a common continuation region and a transition region as discussed in the work of Buffington and Elliott [10]. As a result, the stock price, S , is in the common continuation region if $0 \leq S \leq S_{f2}$, and in the transition region if $S_{f2} \leq S \leq S_{f1}$ as shown in Figure 2.1. The PDE system for each region is presented in the following subsections.

Figure 2.1: The option pricing domain with two optimal exercise boundaries

2.1 Common Continuation Region

In the common continuation region ($0 \leq S \leq S_{f2}$), there are two coupled equations governing option values V_1 and V_2 :

$$\begin{cases} \frac{\partial V_1}{\partial t} + \frac{1}{2} \sigma_1^2 S^2 \frac{\partial^2 V_1}{\partial S^2} + (r - \delta) S \frac{\partial V_1}{\partial S} - r V_1 = \lambda_{12} (V_1 - V_2) \\ \frac{\partial V_2}{\partial t} + \frac{1}{2} \sigma_2^2 S^2 \frac{\partial^2 V_2}{\partial S^2} + (r - \delta) S \frac{\partial V_2}{\partial S} - r V_2 = \lambda_{21} (V_2 - V_1) \end{cases} \quad (2.4)$$

An option will be worthless when the stock price is zero. At the end of the contract, the value

of an option should be equal to its payoff function. Therefore, we have

$$V_i(0, t) = 0 \quad (2.5)$$

$$V_i(S, T) = \max(S - K, 0) \quad (2.6)$$

The optimal exercise price S_{f1} is outside of the common continuation region, so equations (2.5) and (2.6) are the only conditions for option value V_1 .

The optimal exercise price S_{f2} bounds the common continuation region. Thus, at $S = S_{f2}(t)$, V_2 needs to satisfy the following boundary conditions:

$$\begin{cases} V_2(S_{f2}, t) = S_{f2}(t) - K \\ \frac{\partial V_2}{\partial S}(S_{f2}, t) = 1 \end{cases} \quad (2.7)$$

2.2 Transition Region

In the transition region, $S_{f2} \leq S \leq S_{f1}$, the value of V_2 is just the intrinsic value, that is, $V_2 = S - K$. Thus, the PDE system for this region contains only V_1 as an unknown function.

$$\begin{cases} \frac{\partial V_1}{\partial t} + \frac{1}{2}\sigma_1^2 S^2 \frac{\partial^2 V_1}{\partial S^2} + (r - \delta)S \frac{\partial V_1}{\partial S} - rV_1 = \lambda_{12}(V_1 - (S - K)) \\ V_1(S, T) = \max(S - K, 0) \\ V_1(S_{f1}, t) = S_{f1} - K \\ \frac{\partial V_1}{\partial S}(S_{f1}, t) = 1 \end{cases} \quad (2.8)$$

Note that the terminal condition $V_1(S, T) = S - K$, since in the transition region $S > K$.

2.3 Continuity Condition

Since the pricing domain for V_1 consists of two regions, it is necessary to assure the continuity and smoothness of V_1 at the intersection, that is, at $S = S_{f2}$. Therefore,

$$\begin{aligned} \lim_{S \rightarrow S_{f2}^-} V_1 &= \lim_{S \rightarrow S_{f2}^+} V_1 \\ \lim_{S \rightarrow S_{f2}^-} \frac{\partial V_1}{\partial S} &= \lim_{S \rightarrow S_{f2}^+} \frac{\partial V_1}{\partial S} \end{aligned} \quad (2.9)$$

Equations (2.4)-(2.9) form the complete PDE system for the pricing of an American call under a two-state regime-switching economy. We will discuss the solution procedures in the following section.

3 Our Solution Procedure

Before we start to solve the PDE systems, the following change of variables is introduced:

$$X = \frac{S}{K}, \quad \tau = T - t, \quad U_i = \frac{V_i}{K}, \quad i = 1, 2$$

The resulting PDE systems in the common continuation region are:

$$\left\{ \begin{array}{l} -\frac{\partial U_1}{\partial \tau} + \frac{1}{2}\sigma_1^2 X^2 \frac{\partial^2 U_1}{\partial X^2} + (r - \delta)X \frac{\partial U_1}{\partial X} - rU_1 = \lambda_{12}(U_1 - U_2) \\ U_1(0, \tau) = 0 \\ U_1(X, 0) = \max(X - 1, 0) \\ -\frac{\partial U_2}{\partial \tau} + \frac{1}{2}\sigma_2^2 X^2 \frac{\partial^2 U_2}{\partial X^2} + (r - \delta)X \frac{\partial U_2}{\partial X} - rU_2 = \lambda_{21}(U_2 - U_1) \\ U_2(0, \tau) = 0 \\ U_2(X, 0) = \max(X - 1, 0) \\ U_2(X_{f2}, \tau) = X_{f2} - 1 \\ \frac{\partial U_2}{\partial X}(X_{f2}, \tau) = 1 \end{array} \right. \quad (3.1)$$

where $\tau \in [0, T]$, $X \in [0, X_{f2}]$.

The PDE system in the transition region is:

$$\left\{ \begin{array}{l} -\frac{\partial U_1}{\partial \tau} + \frac{1}{2}\sigma_1^2 X^2 \frac{\partial^2 U_1}{\partial X^2} + (r - \delta)X \frac{\partial U_1}{\partial X} - rU_1 = \lambda_{12}[U_1 - (X - 1)] \\ U_1(X, 0) = X - 1 \\ U_1(X_{f1}, \tau) = X_{f1} - 1 \\ \frac{\partial U_1}{\partial X}(X_{f1}, \tau) = 1 \end{array} \right. \quad (3.2)$$

where $\tau \in [0, T]$, $X \in [X_{f2}, X_{f1}]$.

The continuity conditions become:

$$\begin{aligned} \lim_{X \rightarrow X_{f2}^-} U_1 &= \lim_{X \rightarrow X_{f2}^+} U_1 \\ \lim_{X \rightarrow X_{f2}^-} \frac{\partial U_1}{\partial X} &= \lim_{X \rightarrow X_{f2}^+} \frac{\partial U_1}{\partial X} \end{aligned} \quad (3.3)$$

We apply the Laplace transform method to solve the PDE systems in (3.1) and (3.2) with the conditions in (3.3). The pricing PDE systems are transformed into a set of ODE systems in the Laplace space. Zhu's approach in [46] for the treatment of the free boundary or optimal exercise price in the Laplace space is adopted, that is, the moving boundary $X_i = X_{fi}(\tau)$ is replaced by

$X_i = p\bar{X}_{fi}(p)$ in the Laplace space, where

$$\bar{X}_{fi}(p) = \int_0^\infty X_{fi}(\tau) e^{-p\tau} d\tau, \quad i = 1, 2.$$

The solutions of the ODE system as the result of the Laplace transform of the PDE system (3.1) are (see Appendix A for detail):

$$\bar{U}_1(X, p) = \begin{cases} A_1 X^{k_1} + A_2 X^{k_2} + A_3 X^{k_3} + A_4 X^{k_4} + \phi(X, p), & \text{if } 1 < X \leq X_{f2}; \\ A_5 X^{k_3} + A_6 X^{k_4}, & \text{if } 0 \leq X \leq 1; \end{cases} \quad (3.4)$$

$$\bar{U}_2(X, p) = \begin{cases} B_1 X^{k_1} + B_2 X^{k_2} + B_3 X^{k_3} + B_4 X^{k_4} + \phi(X, p), & \text{if } 1 < X \leq X_{f2}; \\ B_5 X^{k_3} + B_6 X^{k_4}, & \text{if } 0 \leq X \leq 1; \end{cases} \quad (3.5)$$

where

$$\phi(X, p) = \frac{1}{p + \delta} X - \frac{1}{p + r},$$

$k_1 < k_2 < 0 < k_3 < k_4$ are the roots of the quartic indicial equation for the ODE system, A_i and B_i , $i = 1, 2, 3 \dots 6$, are some constants in the Laplace space. Note that A_i and B_i are related so only A_i appear in the final equations. The details for finding the quartic roots, and the constants are presented in Appendix C.

The solution of the ODE in the Laplace space corresponding to the PDE system (3.2) in the transition region is (detail in Appendix B):

$$\bar{U}_1(X, p) = m_1 X^{\gamma_1} + m_2 X^{\gamma_2} + \psi_1 X - \psi_2, \quad X_{f2} \leq X \leq X_{f1} \quad (3.6)$$

where

$$\psi_1 = \frac{p + \lambda_{12}}{p(p + \delta + \lambda_{12})}, \quad \psi_2 = \frac{p + \lambda_{12}}{p(p + r + \lambda_{12})},$$

m_1 and m_2 are integration constants, and γ_1 and γ_2 are the solutions to the indicial equation:

$$\frac{1}{2} \sigma_1^2 \gamma^2 + (r - \delta - \frac{1}{2} \sigma_1^2) \gamma - (p + r + \lambda_{12}) = 0.$$

Applying the necessary boundary conditions and continuity conditions to solutions (3.4), (3.5),

and (3.6), we obtain the following equations

$$\begin{cases} A_1 + A_2 + A_3 + A_4 + \frac{1}{p+\delta} - \frac{1}{p+r} = A_5 + A_6 \\ A_1 k_1 + A_2 k_2 + A_3 k_3 + A_4 k_4 + \frac{1}{p+\delta} = A_5 k_3 + A_6 k_4 \\ A_1 l_1 + A_2 l_2 + A_3 l_3 + A_4 l_4 + \frac{1}{p+\delta} - \frac{1}{p+r} = A_5 l_3 + A_6 l_4 \\ A_1 l_1 k_1 + A_2 l_2 k_2 + A_3 l_3 k_3 + A_4 l_4 k_4 + \frac{1}{p+\delta} = A_5 l_3 k_3 + A_6 l_4 k_4 \end{cases} \quad (3.7)$$

$$\begin{cases} A_1 l_1 (p\bar{X}_{f2})^{k_1} + A_2 l_2 (p\bar{X}_{f2})^{k_2} + A_3 l_3 (p\bar{X}_{f2})^{k_3} + A_4 l_4 (p\bar{X}_{f2})^{k_4} + \frac{1}{p+\delta} (p\bar{X}_{f2}) - \frac{1}{p+r} \\ = \frac{1}{p} (p\bar{X}_{f2}) - \frac{1}{p} \\ A_1 l_1 k_1 (p\bar{X}_{f2})^{k_1-1} + A_2 l_2 k_2 (p\bar{X}_{f2})^{k_2-1} + A_3 l_3 k_3 (p\bar{X}_{f2})^{k_3-1} + A_4 l_4 k_4 (p\bar{X}_{f2})^{k_4-1} + \frac{1}{p+\delta} \\ = \frac{1}{p} \end{cases} \quad (3.8)$$

$$\begin{cases} m_1 (p\bar{X}_{f1})^{\gamma_1} + m_2 (p\bar{X}_{f1})^{\gamma_2} + \psi_1 (p\bar{X}_{f1}) - \psi_2 = \frac{1}{p} (p\bar{X}_{f1}) - \frac{1}{p} \\ m_1 \gamma_1 (p\bar{X}_{f1})^{\gamma_1-1} + m_2 \gamma_2 (p\bar{X}_{f1})^{\gamma_2-1} + \psi_1 = \frac{1}{p} \end{cases} \quad (3.9)$$

$$\begin{cases} A_1 (p\bar{X}_{f2})^{k_1} + A_2 (p\bar{X}_{f2})^{k_2} + A_3 (p\bar{X}_{f2})^{k_3} + A_4 (p\bar{X}_{f2})^{k_4} + \frac{1}{p+\delta} (p\bar{X}_{f2}) - \frac{1}{p+r} \\ = m_1 (p\bar{X}_{f2})^{\gamma_1} + m_2 (p\bar{X}_{f2})^{\gamma_2} + \psi_1 (p\bar{X}_{f2}) - \psi_2 \\ A_1 k_1 (p\bar{X}_{f2})^{k_1-1} + A_2 k_2 (p\bar{X}_{f2})^{k_2-1} + A_3 k_3 (p\bar{X}_{f2})^{k_3-1} + A_4 k_4 (p\bar{X}_{f2})^{k_4-1} + \frac{1}{p+\delta} \\ = m_1 \gamma_1 (p\bar{X}_{f2})^{\gamma_1-1} + m_2 \gamma_2 (p\bar{X}_{f2})^{\gamma_2-1} + \psi_1 \end{cases} \quad (3.10)$$

Equations (3.7 - 3.10) consist of 8 unknown constants and 2 unknown dimensionless optimal exercise prices, $\bar{X}_{f1}$ and $\bar{X}_{f2}$. It would be extremely difficult and time consuming to solve the 10 equations simultaneously due to the high non-linearity of the terms involving $\bar{X}_{f1}$ and $\bar{X}_{f2}$. Instead, we solve the equations ‘by parts’, that is, in blocks to obtain all constants and eventually the equations for solving $\bar{X}_{f1}$ and $\bar{X}_{f2}$.

Because the algebraic manipulations are quite tedious, here we only outline the solution procedures and list all constants in Appendix D.

- Since Equation system (3.7) is independent of $\bar{X}_{f1}$ and $\bar{X}_{f2}$, it is solved first to obtain A_1 , A_2 , $A_3 - A_5$ and $A_4 - A_6$.

- A_3 and A_4 are then obtained in terms of $\bar{X}_{f2}$ by substituting the now known A_1 and A_2 in Equation system (3.8).
- Once A_3 and A_4 are solved, A_5 and A_6 will follow.
- m_1 and m_2 are computed from Equation system (3.9) in terms of $\bar{X}_{f1}$.

Plugging in all necessary constants into Equation system (3.10), after some algebraic manipulations, we obtain the following coupled equation system for the computation of $\bar{X}_{f1}$ and $\bar{X}_{f2}$, the optimal exercise prices in the Laplace space:

$$\begin{pmatrix} (p\bar{X}_{f1})^{-\gamma_1} & 0 \\ 0 & (p\bar{X}_{f1})^{-\gamma_2} \end{pmatrix} F_1(p\bar{X}_{f1}) = \begin{pmatrix} (p\bar{X}_{f2})^{-\gamma_1} & 0 \\ 0 & (p\bar{X}_{f2})^{-\gamma_2} \end{pmatrix} F_2(p\bar{X}_{f2}) \quad (3.11)$$

where

$$F_1(p\bar{X}_{f1}) = a_1 + a_2(p\bar{X}_{f1}),$$

$$a_1 = \frac{1}{\gamma_2 - \gamma_1} \begin{pmatrix} -\gamma_2 \\ \gamma_1 \end{pmatrix} \begin{pmatrix} \frac{1}{p} - \psi_2 \end{pmatrix},$$

$$a_2 = \frac{\bar{\psi}_1}{\gamma_2 - \gamma_1} \begin{pmatrix} \gamma_2 - 1 \\ 1 - \gamma_1 \end{pmatrix} \begin{pmatrix} \frac{1}{p} - \psi_1 \end{pmatrix},$$

$$F_2(p\bar{X}_{f2}) = b_1 + b_2(p\bar{X}_{f2}) + b_3 \begin{pmatrix} (p\bar{X}_{f2})^{k_3} & 0 \\ 0 & (p\bar{X}_{f2})^{k_4} \end{pmatrix} \begin{pmatrix} A_3 \\ A_4 \end{pmatrix}$$

$$b_1 = - \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ k_1 & k_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 \\ l_1 k_1 & l_2 k_2 \end{pmatrix}^{-1} \begin{pmatrix} \frac{r}{p(p+r)} \\ 0 \end{pmatrix} + \begin{pmatrix} \frac{p}{p(p+r)} - \psi_2 \\ 0 \end{pmatrix} \right]$$

$$b_2 = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ k_1 & k_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 \\ l_1 k_1 & l_2 k_2 \end{pmatrix}^{-1} \begin{pmatrix} \frac{\delta}{p(p+\delta)} \\ \frac{\delta}{p(p+\delta)} \end{pmatrix} + \begin{pmatrix} \frac{p}{p(p+\delta)} - \psi_1 \\ \frac{p}{p(p+\delta)} - \psi_1 \end{pmatrix} \right]$$

$$b_3 = - \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ k_1 & k_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 \\ l_1 k_1 & l_2 k_2 \end{pmatrix}^{-1} \begin{pmatrix} l_3 & l_4 \\ l_3 k_3 & l_4 k_4 \end{pmatrix} - \begin{pmatrix} 1 & 1 \\ k_3 & k_4 \end{pmatrix} \right]$$

Once A_3 and A_4 are substituted in F_2 , Equation system (3.11) is ready to be solved to obtain $\bar{X}_{f1}$ and $\bar{X}_{f2}$, the optimal exercise prices in Laplace space. This is the limit to our analytic derivation as Equation (3.11) is highly non-linear, it is not possible to obtain an explicit solution. However, the value of Equation (3.11) should not be discounted due to its complicated nature, as the ability to find the optimal exit boundary is crucial for solving an American option problem.

An appropriate numerical technique, `fsolve` in MATLAB, is implemented to first solve Equation (3.11) for $\bar{X}_{f1}$ and $\bar{X}_{f2}$ given p . A good choice for initial input values can speed up computation. For this purpose, we used the theoretical values of the corresponding perpetual functions and the values of the optimal exercise prices at expiry to construct a simple initial guessing function. After the values of the optimal exercise boundaries are computed, it is straightforward to calculate $\bar{U}_1$ and $\bar{U}_2$, the values of the option in Laplace space, using Equations (3.4), (3.5) and (3.6). A numerical Laplace inversion technique is then needed to obtain the values in the original time space. There are several methods for numerical inversion, the Stehfest method ($N = 4$ or $N = 6$) is used in this study due to its simplicity and reliability as pointed out in [49].

It is worth to point it out that although our approach does not produce a final analytical solution, and indeed one can solve Equation (2.4) or Equation (2.8) by some numerical method, such as FDM and FEM, our solution procedure is analytic until the final equation, (3.11). Only then numerical evaluation is needed to solve the highly non-linear coupled equations for the optimal prices in the Laplace space and to find their Laplace inversion. In fact from numerical point view, the computation involved in numerical evaluation of an analytical approach is always much less than solving PDEs directly through a numerical solution procedure, not to mention convergence and stability issues in any purely numerical approach. In addition, computation of Greeks, which are important for hedging purposes, is hard for purely numerical methods to achieve, whereas it can be easily carried out using our approach since we have analytical expressions for the option prices in the Laplace space.

4 Numerical Examples and Discussion

We now present numerical examples to validate our semi-analytic method described above and verify its accuracy and efficiency. In all our calculations, MATLAB 2013 and a PC with the following details were used: Intel(R) Core(TM) i7, CPU 860@2.80 GHz, 4 GB RAM, Windows 7 enterprise service pack 1, 64 bit operating system.

4.1 Method Validation

The results from our calculations are compared with those in the literature first to provide validation for our method. Note that we compare our results for American puts with those from others because we could not find numerical results for the call counterpart in the literature. The formulas to evaluate American put options under a regime-switching economy can be obtained in

a similar way to those for the call counterpart in the previous section. Alternatively, the call formulas can be used to obtain the put results by using Put-Call symmetry [40]. Therefore, we will not present detailed formulation here. Two examples are discussed, one for perpetual American puts, and one for short term American puts.

4.1.1 Perpetual American puts

A perpetual option does not expire so its value is independent of time. As a result, the time derivative term in the governing equations (2.4) and (2.8) drops out. Close-form solutions exist for the case of perpetual American puts with regime switching [20]. Theoretically, if the expiry date $T \rightarrow \infty$ one should be able to recover the the perpetual solution from the finite expiry solution. In order to validate our formulation, we calculate values of optimal exercise prices by letting T be a large number, and compare our results with those of perpetual American puts under a regime-switching economy obtained by the analytic method in [20]. For the sake of comparison, the same parameters are used. The comparison results are shown in Table 1.

Table 1: **Optimal Exercise Price of Perpetual American Puts**

$$r = 0.03, \delta = 0, \sigma_1 = 0.9, \sigma_2 = 0.5, \lambda_{12} = \lambda_{21} = 1, \text{ and } K = 5$$

Analytic results [20]		Our Results	
S_{f1}	S_{f2}	S_{f1}	S_{f2}
0.44055	0.61156	0.44059	0.61163

It is evident that our results are very close to the analytical results of [20], with a maximum relative error less than 0.1%. This indicates that our formula for finite expiry will degenerate to that for perpetual American options with regime-switching as T tends very large. We will next check if the method also performs well for evaluating American options with finite expiry dates.

4.1.2 Finite expiry American puts

We now compare the values of one-year American puts under a regime-switching economy in dimensional variables with those of [40]. The same parameters are used for the sake of comparison. Table 2 displays a comparison of our results with those by the Crank-Nicholson method (CN12800) and the Lattice method (LM51200) in [40].

As displayed in the table, our results compare well with the published values. Most of our results differ from the 'true' values within 1% with a maximum discrepancy of approximately 2%. Our method produces more accurate results as the contract term becomes longer, and it has a maximum relative error of 0.1% for perpetual American puts. For the shorter term contracts, the efficiency in terms of our time savings far outweigh the slight differences in values. It only

Table 2: **One-year American Put Value with Regime-Switching at $t = 0$**

$r = 0.1$, $\delta = 0$, $\sigma_1 = 0.4$, $\sigma_2 = 0.2$, $\lambda_{12} = 1.375968919$, $\lambda_{21} = 1.031976689$ and $K = \$100$

S	CN12800 [40]		LM51200 [40]		Our Results	
$\$$	V_1	V_2	V_1	V_2	V_1	V_2
70	30.0007	30.0000	30.0006	30.0000	29.7706	30.0000
80	21.2289	20.0000	21.2289	20.0000	21.0775	20.0000
90	14.6191	11.6126	14.6190	11.6125	14.4933	11.3834
100	9.9245	6.7423	9.9245	6.7423	9.8786	6.7559
110	6.7017	3.9244	6.7017	3.9243	6.5957	3.8604
120	4.5257	2.3083	4.5257	2.3083	4.4568	2.2928
130	3.0665	1.3825	3.0665	1.3825	3.0488	1.3879
140	2.0889	0.8460	2.0889	0.8460	2.0627	0.8564
150	1.4318	0.5287	1.4318	0.5287	1.4170	0.5368

takes maximum 0.3 seconds to obtain an option value as well as the optimal boundaries using our formula, whereas 12800 and 51200 time steps are needed to obtain the ‘true’ values in the Crank-Nicholson method and the Lattice method, respectively.

4.2 Finite Expiry American calls

In this example, we present our calculation of the optimal exercise prices and the values of American call options with finite expiry date in a regime-switching economy. The parameters used in the calculations are: $r = 0.06$, $\delta = 0.08$, $\sigma_1 = 0.3$, $\sigma_2 = 0.2$, $\lambda_{12} = 1.375968919$, $\lambda_{21} = 1.031976689$, $K = \$100$, and $T = 1$ year.

The dimensionless optimal exercise prices of one-year American call options under a regime-switching economy are illustrated together with option values calculated under the classical Black-Scholes model in Figure 4.2 with ns indicating non-switching (B-S) model and rs indicating regime-switching model. As expected, the optimal exercise prices with regime-switching are bounded between those for the standard American calls; the optimal exercise price in the growth phase of the economy (σ_1) is lower than that of the corresponding Black-Scholes model due to the possibility that the economy may change to the recession phase (σ_2), and vice versa for the optimal exercise price in the recession phase of the economy (σ_2).

The values of a one-year American call option under a regime-switching economy for various stock price S are presented, and compared with those for standard American calls in Table 3. Again the results verify the theoretical analysis that the values with regime-switching should be between those of the non-switching model in [42], the values of American call under a regime-switching economy are between those of standard American calls, that is, $V_2^{BS} < V_2 < V_1 < V_1^{BS}$ for $\sigma_2 < \sigma_1$.

The effect of changing the dividend rate δ and the risk-free interest rate r are displayed in

Figure 4.2: Dimensionless optimal exercise prices

Table 3: **One-year American Call Option Values at $t = 0$**

$r = 0.06, \delta = 0.08, \sigma_1 = 0.3, \sigma_2 = 0.2,$
 $\lambda_{12} = 1.375968919, \lambda_{21} = 1.031976689$ and $K = 100$

S	Our results		BS	
	V_1	V_2	V_1	V_2
80	2.264831	1.47024	2.9753	0.91842
100	9.351436	7.78078	10.465	6.7532
120	22.50430	20.71355	23.143	20.288

Figure 4.3 and Figure 4.4, respectively. The sensitivity of the key parameters follows the same trend as that of an American call option in a non-switching economy.

5 Concluding remarks

In this paper, we develop a modified semi-analytical method to evaluate American options under a two-state regime-switching economy. Numerical examples for American options in finite and infinite maturity are presented, and the results compare well with those of existing methods. Further, the results show that our method provides an efficient as well as accurate valuation,

Figure 4.3: Dimensionless optimal exercise prices for different dividend rate

Figure 4.4: Dimensionless optimal exercise prices for different interest rate

especially for longer term contracts.

The approach could be adopted to the evaluation of American barrier options under a regime-switching economy. The easiest example is American down-and-out options, only the lower boundary condition needs to be changed, that is, homogeneous boundary conditions at the barrier instead of at the zero stock value. The derivation of the final equations would be similar, but

more tedious, as we have two extra constants to be decided. However, for other types of barrier options, it is not straight forward. Indeed it is part of our plan for future research.

Appendix A Solution for Common Continuation Region

In this appendix the PDE systems in equation (3.1) are solved by following the technique in [46].

Employing two intervals in the common continuation region, $1 < X \leq X_{f2}$ and $X \leq 1$, the PDE system for U_1 in equation (3.1) can be presented as follows:

$$\left\{ \begin{array}{ll} -\frac{\partial U_1}{\partial \tau} + \frac{1}{2}\sigma_1^2 X^2 \frac{\partial^2 U_1}{\partial X^2} + (r - \delta)X \frac{\partial U_1}{\partial X} - rU_1 = \lambda_{12}(U_1 - U_2), & \text{if } 1 < X \leq X_{f2}; \\ U_1(0, \tau) = 0 \\ U_1(X, 0) = X - 1 \\ -\frac{\partial U_1}{\partial \tau} + \frac{1}{2}\sigma_1^2 X^2 \frac{\partial^2 U_1}{\partial X^2} + (r - \delta)X \frac{\partial U_1}{\partial X} - rU_1 = \lambda_{12}(U_1 - U_2), & \text{if } X \leq 1; \\ U_1(0, \tau) = 0 \\ U_1(X, 0) = 0 \end{array} \right. \quad (\text{A.1})$$

The following continuity conditions are enforced to ensure that U_1 is C^1 continuous at $X = 1$:

$$\left\{ \begin{array}{l} \lim_{x \rightarrow 1^-} U_1 = \lim_{x \rightarrow 1^+} U_1 \\ \lim_{x \rightarrow 1^-} \frac{\partial U_1}{\partial X} = \lim_{x \rightarrow 1^+} \frac{\partial U_1}{\partial X} \end{array} \right. \quad (\text{A.2})$$

Similarly, the PDE system for U_2 becomes:

$$\left\{ \begin{array}{ll} -\frac{\partial U_2}{\partial \tau} + \frac{1}{2}\sigma_2^2 X^2 \frac{\partial^2 U_2}{\partial X^2} + (r - \delta)X \frac{\partial U_2}{\partial X} - rU_2 = \lambda_{21}(U_2 - U_1), & \text{if } 1 < X \leq X_{f2}; \\ U_2(0, \tau) = 0 \\ U_2(X, 0) = X - 1 \\ U_2(X_{f2}, \tau) = X_{f2} - 1 \\ \frac{\partial U_2}{\partial X}(X_{f2}, \tau) = 1 \\ -\frac{\partial U_2}{\partial \tau} + \frac{1}{2}\sigma_2^2 X^2 \frac{\partial^2 U_2}{\partial X^2} + (r - \delta)X \frac{\partial U_2}{\partial X} - rU_2 = \lambda_{21}(U_2 - U_1), & \text{if } X \leq 1; \\ U_2(0, \tau) = 0 \\ U_2(X, 0) = 0 \end{array} \right. \quad (\text{A.3})$$

with the continuity conditions at $X = 1$:

$$\begin{cases} \lim_{x \rightarrow 1^-} U_2 = \lim_{x \rightarrow 1^+} U_2 \\ \lim_{x \rightarrow 1^-} \frac{\partial U_2}{\partial X} = \lim_{x \rightarrow 1^+} \frac{\partial U_2}{\partial X} \end{cases} \quad (\text{A.4})$$

Subsequently, equations (A.1 - A.4) are transformed to the Laplace space as follows

$$\begin{cases} \frac{1}{2}\sigma_1^2 X^2 \frac{d^2 \bar{U}_1}{dX^2} + (r - \delta)X \frac{d\bar{U}_1}{dX} - (p + r + \lambda_{12})\bar{U}_1 + \lambda_{12}\bar{U}_2 = -(X - 1), & \text{if } 1 < X \leq X_{f1}; \\ \bar{U}_1(0, p) = 0 \\ \frac{1}{2}\sigma_1^2 X^2 \frac{d^2 \bar{U}_1}{dX^2} + (r - \delta)X \frac{d\bar{U}_1}{dX} - (p + r + \lambda_{12})\bar{U}_1 + \lambda_{12}\bar{U}_2 = 0, & \text{if } X \leq 1; \\ \bar{U}_1(0, p) = 0 \end{cases} \quad (\text{A.5})$$

$$\begin{cases} \bar{U}_1(1^-, p) = \bar{U}_1(1^+, p) \\ \frac{d\bar{U}_1}{dX}(1^-, p) = \frac{d\bar{U}_1}{dX}(1^+, p) \end{cases} \quad (\text{A.6})$$

$$\begin{cases} \frac{1}{2}\sigma_2^2 X^2 \frac{d^2 \bar{U}_2}{dX^2} + (r - \delta)X \frac{d\bar{U}_2}{dX} - (p + r + \lambda_{21})\bar{U}_2 + \lambda_{21}\bar{U}_1 = -(X - 1), & \text{if } 1 < X \leq X_{f2}; \\ \bar{U}_2(0, p) = 0 \\ \bar{U}_2(p\bar{X}_{f2}, p) = \bar{X}_{f2} - \frac{1}{p} \\ \frac{d\bar{U}_2}{dX}(p\bar{X}_{f2}, p) = \frac{1}{p} \\ \frac{1}{2}\sigma_2^2 X^2 \frac{d^2 \bar{U}_2}{dX^2} + (r - \delta)X \frac{d\bar{U}_2}{dX} - (p + r + \lambda_{21})\bar{U}_2 + \lambda_{21}\bar{U}_1 = 0, & \text{if } X \leq 1; \\ \bar{U}_2(0, p) = 0 \end{cases} \quad (\text{A.7})$$

$$\begin{cases} \bar{U}_2(1^-, p) = \bar{U}_2(1^+, p) \\ \frac{d\bar{U}_2}{dX}(1^-, p) = \frac{d\bar{U}_2}{dX}(1^+, p) \end{cases} \quad (\text{A.8})$$

Equations (A.5 - A.8) are ODE systems which are easier to be solved. In performing the Laplace transform, the pseudo-steady-state approximation proposed by Zhu [46] is applied to the free boundary.

The solutions to the ODE systems are in the following form:

$$\bar{U}_1(X, p) = \begin{cases} A_1 X^{k_1} + A_2 X^{k_2} + A_3 X^{k_3} + A_4 X^{k_4} + AA(X, p), & \text{if } 1 < X \leq X_{f2}; \\ A_5 X^{k_1} + A_6 X^{k_2} + A_7 X^{k_3} + A_8 X^{k_4}, & \text{if } X \leq 1; \end{cases} \quad (\text{A.9})$$

$$\bar{U}_2(X, p) = \begin{cases} B_1 X^{k_1} + B_2 X^{k_2} + B_3 X^{k_3} + B_4 X^{k_4} + BB(X, p), & \text{if } 1 < X \leq X_{f2}; \\ B_5 X^{k_1} + B_6 X^{k_2} + B_7 X^{k_3} + B_8 X^{k_4}, & \text{if } X \leq 1; \end{cases} \quad (\text{A.10})$$

where

$$AA(X, p) = BB(X, p) = \frac{1}{p + \delta} X - \frac{1}{p + r}.$$

The constants A_i and B_i are related by the following equation:

$$\left\{ \frac{1}{2} \sigma_1^2 k_i (k_i - 1) + (r - \delta) k_i - (p + r + \lambda_{12}) \right\} A_i + \lambda_{12} B_i = 0$$

or

$$\left\{ \frac{1}{2} \sigma_2^2 k_i (k_i - 1) + (r - \delta) k_i - (p + r + \lambda_{21}) \right\} B_i + \lambda_{21} A_i = 0$$

where k_i , $i = 1 \dots 4$ are the solutions to the quartic indicial equation (C.2). Further, in Appendix C we proved that

$$k_1 < k_2 < 0 < k_3 < k_4.$$

Recall the boundary condition $\bar{U}_{1,2}(0, p) = 0$, it is apparent that the solutions in the region $X < 1$ can not involve negative powers of X . This means that the coefficients of X^{k_1} and X^{k_2} in the solutions for $X < 1$ should be zero, that is, $A_5 = A_6 = B_5 = B_6 = 0$. Renaming the constants A_7, A_8 and B_7, B_8 to A_5, A_6 and B_5, B_6 , we obtain the final solutions of $\bar{U}_1$ and $\bar{U}_2$ in the Laplace space:

$$\bar{U}_1(X, p) = \begin{cases} A_1 X^{k_1} + A_2 X^{k_2} + A_3 X^{k_3} + A_4 X^{k_4} + AA(X, p), & \text{if } 1 < X \leq X_{f2}; \\ A_5 X^{k_3} + A_6 X^{k_4}, & \text{if } X \leq 1; \end{cases} \quad (\text{A.11})$$

$$\bar{U}_2(X, p) = \begin{cases} B_1 X^{k_1} + B_2 X^{k_2} + B_3 X^{k_3} + B_4 X^{k_4} + BB(X, p), & \text{if } 1 < X \leq X_{f2}; \\ B_5 X^{k_3} + B_6 X^{k_4}, & \text{if } X \leq 1; \end{cases} \quad (\text{A.12})$$

The fact that A_i are related to B_i allows us to solve only for the A_i 's in the final equations.

Appendix B Solution for Transition Region

In this appendix, we present the steps to solve the PDE system in transition region. We start by transforming the equation system (3.2) into the Laplace space:

$$\begin{cases} \frac{1}{2}\sigma_1^2 X^2 \frac{d^2 \bar{U}_1}{dX^2} + (r - \delta)X \frac{d\bar{U}_1}{dX} - (p + r + \lambda_{12})\bar{U}_1 = -(X - 1) - \frac{\lambda_{12}(X - 1)}{p} \\ \bar{U}_1(p\bar{X}_{f1}, p) = \bar{X}_{f1} - \frac{1}{p} \\ \frac{d\bar{U}_1}{dX}(p\bar{X}_{f1}, p) = \frac{1}{p} \end{cases} \quad (\text{B.1})$$

The solution of equation (B.1) has a general form of

$$\bar{U}_1 = m_1 X^{\gamma_1} + m_2 X^{\gamma_2} + M(X, p) \quad (\text{B.2})$$

where $m_{1,2}$ are integration constants, $\gamma_{1,2}$ are the solutions of the indicial equation

$$\frac{1}{2}\sigma_1^2 \gamma^2 + (r - \delta - \frac{1}{2}\sigma_1^2)\gamma - (p + r + \lambda_{12}) = 0, \quad (\text{B.3})$$

and $M(X, p)$ is the particular solution of equation (B.1),

$$M(X, p) = \left\{ \frac{p + \lambda_{12}}{p(p + \delta + \lambda_{12})} \right\} X - \left\{ \frac{p + \lambda_{12}}{p(p + r + \lambda_{12})} \right\}$$

or we can write as follows:

$$M(X, p) = \psi_1 X - \psi_2$$

where

$$\psi_1 = \left\{ \frac{p + \lambda_{12}}{p(p + \delta + \lambda_{12})} \right\}$$

and

$$\psi_2 = \left\{ \frac{p + \lambda_{12}}{p(p + r + \lambda_{12})} \right\}$$

Appendix C Solution of Indicial Equations

The solutions in the Laplace space in the common continuation region are presented in equations (A.9) and (A.10). Substituting these solutions and their derivatives into equations (A.5) and (A.7), we obtain the relation between constants A_i and B_i :

$$\left\{ \frac{1}{2} \sigma_1^2 k_i (k_i - 1) + (r - \delta) k_i - (p + r + \lambda_{12}) \right\} A_i + \lambda_{12} B_i = 0$$

or

$$\left\{ \frac{1}{2} \sigma_2^2 k_i (k_i - 1) + (r - \delta) k_i - (p + r + \lambda_{21}) \right\} B_i + \lambda_{21} A_i = 0$$

The last two equations are equivalent. Let $l(k_i) = \frac{1}{2} \sigma_1^2 k_i (k_i - 1) + (r - \delta) k_i - (p + r + \lambda_{12})$, the relation between A_i and B_i can be expressed as follows

$$B_i = -A_i \frac{l(k_i)}{\lambda_{12}}, \quad \text{for } i = 1 \dots 4 \quad \text{and} \quad B_i = -A_i \frac{l(k_{i-4})}{\lambda_{12}}, \quad \text{for } i = 5 \dots 8 \quad (\text{C.1})$$

Note that for simplicity we use $l_i = l(k_i)$, $i = 1, 2, 3, 4$ in the main sections of this paper.

In common continuation region, the indicial equation for the corresponding differential equations is a quartic equation as written below:

$$F(k) = l(k)g(k) - \lambda_{12}\lambda_{21} \quad (\text{C.2})$$

where $l(k)$ and $g(k)$ are quadratic functions

$$l(k) = \frac{1}{2} \sigma_1^2 k^2 + (r - \delta - \frac{1}{2} \sigma_1^2) k - (p + r + \lambda_{12})$$

and

$$g(k) = \frac{1}{2} \sigma_2^2 k^2 + (r - \delta - \frac{1}{2} \sigma_2^2) k - (p + r + \lambda_{21}).$$

Let

$$l(k) = \frac{1}{2} \sigma_1^2 k^2 + (r - \delta - \frac{1}{2} \sigma_1^2) k - (p + r + \lambda_{12}) = 0. \quad (\text{C.3})$$

Since $\lim_{k \rightarrow \infty} l(k) = \lim_{k \rightarrow -\infty} l(k) \rightarrow \infty$ and $l(0) = -(p + r + \lambda_{12}) < 0$ ($p, r, \lambda_{12} > 0$), it can be concluded that Equation (C.3) has two real roots, say, $kk_1 < 0$ and $kk_2 > 0$.

Now, $F(kk_1) = F(kk_2) = -\lambda_{12}\lambda_{21} < 0$ ($\lambda_{12}, \lambda_{21} > 0$), $F(0) = (p + r)(p + r + \lambda_{12} + \lambda_{21}) > 0$ and $\lim_{k \rightarrow \infty} F(k) = \lim_{k \rightarrow -\infty} F(k) \rightarrow \infty$. Hence, we can conclude that the quartic function $F(k)$ has four real roots k_1, k_2, k_3, k_4 , two of which are positive and two negative, that is,

$$k_1 < k_2 < 0 < k_3 < k_4.$$

Appendix D List of Integration Constants

Here we list the final result for the integration constants in Section 3 without the tedious algebraic details:

$$\begin{pmatrix} A_1 \\ A_2 \end{pmatrix} = \left[\begin{pmatrix} 1 & 1 \\ k_3 & k_4 \end{pmatrix}^{-1} \begin{pmatrix} 1 & 1 \\ k_1 & k_2 \end{pmatrix} - \begin{pmatrix} l_3 & l_4 \\ l_3 k_3 & l_4 k_4 \end{pmatrix}^{-1} \begin{pmatrix} l_1 & l_2 \\ l_1 k_1 & l_2 k_2 \end{pmatrix} \right]^{-1} \begin{pmatrix} \frac{1}{p+r} - \frac{1}{p+\delta} \\ -\frac{1}{p+\delta} \end{pmatrix} \quad (\text{D.1})$$

$$\begin{pmatrix} A_3 \\ A_4 \end{pmatrix} = \begin{pmatrix} (p\bar{X}_{f2})^{-k_3} & 0 \\ 0 & (p\bar{X}_{f2})^{-k_4} \end{pmatrix} \begin{pmatrix} l_3 & l_4 \\ l_3 k_3 & l_4 k_4 \end{pmatrix}^{-1} \left[\begin{pmatrix} \frac{\delta}{p(p+\delta)}(p\bar{X}_{f2}) - \frac{r}{p(p+r)} \\ \frac{\delta}{p(p+\delta)}(p\bar{X}_{f2}) \end{pmatrix} - \begin{pmatrix} l_1 & l_2 \\ l_1 k_1 & l_2 k_2 \end{pmatrix} \begin{pmatrix} (p\bar{X}_{f2})^{k_1} & 0 \\ 0 & (p\bar{X}_{f2})^{k_2} \end{pmatrix} \right]^{-1} \begin{pmatrix} 1 & 1 \\ k_3 & k_4 \end{pmatrix}^{-1} \begin{pmatrix} 1 & 1 \\ k_1 & k_2 \end{pmatrix} - \begin{pmatrix} l_3 & l_4 \\ l_3 k_3 & l_4 k_4 \end{pmatrix}^{-1} \begin{pmatrix} l_1 & l_2 \\ l_1 k_1 & l_2 k_2 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ k_3 & k_4 \end{pmatrix}^{-1} \begin{pmatrix} l_3 & l_4 \\ l_3 k_3 & l_4 k_4 \end{pmatrix}^{-1} \begin{pmatrix} \frac{1}{p+r} - \frac{1}{p+\delta} \\ -\frac{1}{p+\delta} \end{pmatrix} \quad (\text{D.2})$$

$$\begin{pmatrix} A_5 \\ A_6 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ k_3 & k_4 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ k_1 & k_2 \end{pmatrix} \begin{pmatrix} A_1 \\ A_2 \end{pmatrix} + \begin{pmatrix} 1 & 1 \\ k_3 & k_4 \end{pmatrix} \begin{pmatrix} A_3 \\ A_4 \end{pmatrix} - \begin{pmatrix} \frac{1}{p+r} - \frac{1}{p+\delta} \\ -\frac{1}{p+\delta} \end{pmatrix} \right] \quad (\text{D.3})$$

$$\begin{pmatrix} m_1 \\ m_2 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \begin{pmatrix} (p\bar{X}_{f1})^{\gamma_1} & 0 \\ 0 & (p\bar{X}_{f1})^{\gamma_2} \end{pmatrix} \begin{pmatrix} p\bar{X}_{f1} - 1 \\ p\bar{X}_{f1} \end{pmatrix} \begin{pmatrix} \frac{1}{p} - \psi_2 \end{pmatrix} \quad (\text{D.4})$$
