Synthesis and characterization of additive graphene oxide nanoparticles dispersed in water: Experimental and theoretical viscosity prediction of non-Newtonian nanofluid

Abstract

© 2020 John Wiley & Sons, Ltd. Graphene oxide (GO) is a mixture of carbon, oxygen, and hydrogen. GO sheets used to make tough composite materials, thin films, and membranes. GO-water nanofluid's rheological behavior was investigated in this research. Various mass fractions: 1.0, 1.5, 2.0, 2.5, and 3.5 mg/ml; different temperature ranges: 25°C, 30°C, 35°C, 40°C, 45°C, and 50°C; and several shear ranges: 12.23, 24.46, 36.69, 61.15, 73.38, and 122.3 s⁻¹ were studied. X-ray diffraction analysis (XRD), energy dispersive X-ray analysis (EDX), dynamic light scattering analysis (DLS), and Fourier-transform infrared (FTIR) tests studied to analyze phase and structure. Field emission scanning electron microscope (FESEM) and transmission electron microscopy (TEM) tests studied for microstructural observation. The stability of nanofluid was checked by the zeta-potential test. Non-Newtonian behavior of nanofluid, similar to power-law model (with power less than one), revealed by results. Also, results showed that viscosity increased by increment of mass fraction, and on the contrary, increment of temperature, caused a decrease in viscosity. Then, to calculate nanofluid's viscosity, a correlation presented 1.88% (for RPM = 10) and 0.56% (for RPM = 100) deviation. Finally, to predict nanofluid's viscosity in other mass fractions and temperatures, an artificial neural network has been modeled by R² = 0.99. It can be concluded that GO can be used in thermal systems as stable nanofluid with agreeable viscosity.

Graphical Abstract

1. Introduction

Graphene Oxide (GO), has a two-dimensional structure with superb mechanical and thermal properties [1]. Despite its excellent properties, GO mass-production at a low cost is important. Also, the production method must be eco-friendly due to its usage in biocomposites and biofilms [2]. Indeed, in nature, we can find Graphene sheets; however, the purity is another requirement to produce Graphene Oxide [3]. Production of Graphene from Graphite can be done physically and chemically. For this purpose, the selection of graphite is important and thus, Flake graphite with size less than one mm is required [4]. For useful applications, Graphene Oxide can also be self-assembled or fabricated in macroscopic microstructures and compositions [5]. In the Staudenmaier method (that needs four days), about two-thirds of fuming HNO_3 with concentrated H_2SO_4 replaced and KClO_3 added in multiple portions which allow the reaction in a vessel. Then, a new method introduced by hummers and Offeman (H method) in 1958. This method is widely accepted to synthesis GO and has some advantages. First, its production time reduced to hours instead of days; then, reaction safety increased by adding KMnO_4 instead of KClO_3 , and finally, acid fog eliminated by adding NaNO_3 instead of HNO_3 [6]. Tour and co-workers improved this method (MH method) by excluding NaNO_3 and adding more KMnO_4 [7]. Also, by using an improved Hummers method, Graphene Oxide can be produced without using NaNO_3 which causes more low cost and more eco-friendly effects [8].

In the oil, gas and petrochemical industries, heat exchangers play a major role and thus, more research to improve their efficiency is required. Using nanofluids by different types of nanomaterials and basefluid are recent studies in this field [9]. Due to its important usage in industries, nanofluids should be tested more to understand their properties and their effects. Thermal conductivity, Thermal stability and Viscosity are important properties of a nanofluid [10]. Despite numerous studies in thermal conductivity, limited studies exist on viscosity properties. Totally, Nanofluid is a suspension of particles or tubes with more thermal properties compared to base fluid. Research trends for nanofluid and their properties show global motivation in characterization and usage of nanofluids to gain more advantages. Nanoparticle properties such as shape, size, and also an interaction between nanoparticles and base fluid effects properties [11]. Rheological behavior and aggregate size of nanofluid are related to each other. A nanofluid can show both Newtonian and non-Newtonian behavior. Nanofluid behavior is due to its shape, size and mass fraction.

Many studies conducted to realize properties of nanofluids containing carbon-based materials, such as Graphene, Graphene Oxide and MWCNT [12]. Adding more of carbon-based materials to base fluid, create a gel-like fluid and thus, nanofluid viscosity increase which is undesirable [13]. Due to the unique physicochemical properties of graphene-based materials, and also their compatibility with other compounds, more experiment studies are required. There are few types of research about the effect of particle size and viscosity of graphene oxide nanofluids [14, 46-63].

In this paper, Graphene Oxide synthesized via the MH method. After that, Graphene Oxide added to Water and nanofluid prepared at mass fractions 1.0 to 3.5mg/ml. Then, experiments were done at various temperatures. By curve fitting method, a new correlation presented to calculate the viscosity of Graphene Oxide/Water nanofluid. Finally, artificial neural network modeled data.

2. Materials and Methods

2.1. Materials

With respect to KPA-Iran, Flake graphite (FG) prepared with excellent purity. Also, other materials used in order to synthesis, had excellent purity with analytical grade. Figure 1 shows the Graphene Oxide and Flake Graphite 3D-schematic form. Also, Properties of nanomaterial and basefluid are presented in Table 1.

Table 1. Thermophysical Properties of Base Fluid and Nanoparticle

Properties	Water (Base fluid)	Flake Graphite	Graphene Oxide (Nanoparticle)
Chemical formula	H ₂ O	C	C
Molar mass (g/mol)	18.0153	12.01	12.01
Density (gr/m ³)	~1.0	~2.0	~2.3
Viscosity (mPa.s)	---	---	This paper

Figure 1. Graphene Oxide and Flake Graphite 3D-schematic form

2.2. Powder Synthesis & Nanofluid Preparation

Figure 2. displays synthesis and preparation steps of Graphene Oxide (GO) powder and nanofluid. XRD tested by a D8ADVANCE Bruker X-ray diffractometer. EDX used to confirm XRD results. Also, DLS was measured by VASCO Cordouan Technologies. Then, FTIR spectra was recorded on JASCO 6300JAPAN. Also, FESEM applied to observe sample morphology by NOVA NanoSEM [15].

The first step before thermophysical properties measuring, is the preparation of nanofluid. By adding GO to deionized Water, nanofluid prepared at concentration of 1.0, 1.5, 2.0, 2.5, and 3.5 mg/ml. The total concentration of GO used in nanofluid can be computed from Equation (01). GO mass was measured by digital A&D GF-600 Weighing Lab Balance with 1-mg precision. To prepare the nanofluid, a two-stage method because of its reasonable cost and simplicity was used. In this technique, synthesized material, dispersed in water base fluid by applicable dispersion approach. However, the biggest problem in this method, is agglomeration. To prevent this, and to obtain a good dispersion, pH meter, magnetic stirring (for 100 min), and sonication (for 20 min) with ultrasonic processor 400 W - 24 kHz (Hielscher Company, Germany) is used. Thus, a stable suspension prepared [16].

$$\phi = \left[\frac{\left(\frac{w}{\rho}\right)_{GO}}{\left(\frac{w}{\rho}\right)_{GO} + \left(\frac{w}{\rho}\right)_{Water}} \right] * 100$$

Where ϕ is mass fraction percentage, w indicates mass and ρ is density.

Figure 2. Schematic diagram of powder synthesis steps (Flake Graphite to Graphene Oxide) and also nanofluid preparation

2.3. Viscosity Measurement

To measure GO-Water viscosity, a DV2EXTRAPro rotational viscometer (BROOKFIELD) with

5% error is applied [17]. These viscometers work based on measuring the resistance of the fluid due to the torque created by the spindle that is immersed in the fluid. Further, an precise temperature bath (LAUDA Alpha RA 8) was connected to viscometer to provide temperature stability and also measure the effects of temperature on viscosity of the nanofluid. as a result, it is possible to analyse the viscosity and rheological behavior of nanofluids under the influence of shear rate and temperature at various concentrations. To measure the viscosity of GO-Water, ULA spindle (1-200 RPM/ 1-6 mPa.S with 1.223 shear rate coefficient and a small sample adapter system) is used [18]. Earlier, DV2T was calibrated at room temperature by experiments with distilled water and its data compare with accessible viscosity data for pure water [19]. Viscosity analysis at different shear rates, studied four times for 25, 30, 35, 40, 45 and 50°C temperature, independently. The accuracy and repeatability of the viscometer used are $\pm 0.2\%$ and $\pm 1\%$ in the full-scale range (FSR) of measurements, accordingly. To calculate FSR through Equation (02), the values of torque coefficient (TK), spindle multiplier constant (SMC) and rotational speed of spindle by means of device round per minute (RPM) are needed.

$$FSR(mPa.s) = TK * SMC * \frac{10000}{RPM} \quad (02)$$

The values of TK and SMC for ULA spindle are 0.0937 and 0.64, accordingly. Thus, the repeatability of the results can be computed from Equation (03).

$$Repeatability(mPa.s) = 0.002(FSR) \quad (03)$$

The measurement error for the viscosity of nanofluids in this research can be computed by the Equation (04), in accordance with the user's manual of viscometer.

$$Error(mPa.s) = 0.01(FSR + \mu) \quad (04)$$

In which, $\mu(mPa.s)$ represents the nanofluids viscosity.

3. Result

3.1. Synthesis

3.1.1. Phase Investigation

XRD

Figure 3 displays XRD pattern and crystallinity structure of synthesized GO by MH method. The

sharp (001) peak can be seen at $2\theta = 10.775^\circ$, corresponding to the d-spacing of $8.214 \text{ \AA}$. However, this sharp (002) peak in FG, can be seen at $2\theta = 26.475^\circ$ corresponding to the d-spacing of $3.363 \text{ \AA}$ by Bragg's law ($1.541 \text{ \AA}$ wavelength of Cu $K\alpha$). This means, in the synthesizing process, the crystal plane changed from (002) to (001) which can be seen at 2θ ; Also, d-spacing increased about $4.851 \text{ \AA}$ [20].

Figure 3. XRD comparison between Graphene Oxide (GO) and Graphite (FG)

DLS

DLS used to determine size distribution for FG and GO dispersed in Water. GO has a 2D structure which means only one dimension is at the nanoscale. However, DLS cannot measure the thickness itself, and the size of two other dimensions (which are in microscale) also shown in Figure. Figure 4 shows that GO (About 69.4 vol.% has 474.28 nm) has less volume than Flake Graphite (Around 39.5 vol.% has 653.49 nm) [21].

Figure 4. DLS comparison between Graphene Oxide (GO) and Graphite (FG)

FTIR

Figure 5 shows FTIR spectroscopy analysis. To study structure and functional groups of Flake Graphite and Graphene Oxide, FTIR used. For GO sample, **the** wide peak from 2859.3 to 3720.82 cm^{-1} , which correspond to OH groups of water molecules reported in **the** high-frequency area. Graphene Oxide hydrophilicity can be concluded from this wide peak. carboxyl C=O characteristic peaks of Graphene Oxide, reported in 1738.51 cm^{-1} . To compare both FG and GO, Figure 5 displays **a** lower intensity of FG peaks. As a report, functional groups can be seen as:

O-H, C=C, C-OH and C-O at 3420.14 cm^{-1} , 1622.8 cm^{-1} , 1224.47 cm^{-1} , 1052.94 cm^{-1} , for Graphene Oxide respectively and also C=C, and C-O at 1578.01 cm^{-1} and 1028.32 cm^{-1} for Flake Graphite respectively [22].

Figure 5. FTIR comparison between Graphene Oxide (GO) and Graphite (FG)

3.1.2. Microstructural Observations

FESEM and EDX

Figure 6 displays the FESEM of the disordered and amorphous 2D structure of synthesized GO. It can be seen that GO has a layer structure and its thickness is less than 100nm. The thick structure of GO is because of covalently bound oxygen presence, and it is easy to determine sheets edges. Wrinkled areas are one above the other. GO sheets have 1 - 3 μm flake diameter [23].

EDX test done for 2 points for FG and GO. Figure 7, displays that Flake graphite have around 82.05 at.% C, 14.82 at.% O and 3.13 at.% N + Fe + Si + Al. However, Graphene Oxide has more purity and have around 61.12 at.% C, 37.94 at.% O and 0.94 at.% S.

TEM

Transmission electron microscopy used to confirm that GO thickness is under 100nm. In the TEM technique, to make an image, a beam of electrons transmitted through a specimen. It can be seen in Figure 8 that Graphene Oxide has a 2D layer structure and its thickness is less than 50nm [24].

Figure 8. TEM of Graphene Oxide (GO)

3.2. Generate the Nanofluid

3.2.1. Stability

Zeta Potential

Figure 9 displays the zeta potential of Graphene Oxide at 1.0 and 4.5 mg/ml. GO colloid solution at a pH range of 2–4, displays negative zeta potential. As reported by ASTM, ZP ranges of 20 to 30 mV are moderately stable and $>\pm 30$ mV are highly stable. ZP for mass fractions 1.0 and 4.5 are 36 mV 38.3 mV, respectively, these ZP values, displays high stability of nanomaterial in the aqueous phase. By these ZP values, it can be concluded that GO has aggregation behavior by increasing the mass fraction. By increasing mass fraction, GO negative electrical surface charge, rose which is due to the ionization of carboxylic acid groups [25]. This trend was not seen through the previous works [64-79].

Figure 9. Zeta potential of Graphene Oxide (concentration of 1.0 mg/ml & 4.5 mg/ml)

3.2.2. Viscosity

Validation

First, to confirm viscometer accuracy, DV2T viscometer validity was specified by distilled water (as calibration fluid) and compared to the ASHRAE handbook [26]. The error of device measurement was acceptable (less than 5%) at $T = 25^{\circ}\text{C}$ (regarding its manual). Figure 10, shows maximum error of 4.58% (at $T = 25^{\circ}\text{C}$).

Figure 10. Viscosity of experimental data for pure water versus ASHRAE handbook [26] data by temperature

Mass Fraction and Temperature Effect

Determining nanofluid's rheological behavior whether it shows Newtonian or non-Newtonian behaviors at various mass fractions and temperatures is important [27]. Figure 11 shows viscosity by mass fraction at various temperatures in shear rates of 12.23 and 122.3 [28]. Figure 12 shows viscosity by the temperature at various mass fractions in shear rates of 12.23 and 122.3 [29]. As it can be seen by increasing mass fraction, viscosity increased. However, by increasing in temperature, viscosity decreased. Figure 13 shows 3D results of viscosity by both temperature and mass fraction in shear rates of 12.23 and 122.3.

Figure 11. Viscosity profiles versus concentration

Figure 12. Viscosity profiles versus temperature

Figure 13. Three-dimensional view of Experimental data for viscosity at various nanofluid mass fractions and temperatures and

Non-Newtonian behavior

The rheological behavior of nanofluids could be characterized, because of the flow behavior under applied external pressure and also a response to shear stress. Also, the effects caused by the shear stress are more important than the pressure because most liquids are considered as an incompressible fluid. Fluids have Newtonian behavior when shear stress (τ) is linearly proportional to the shear rate ($\dot{\gamma}$) and their viscosity (μ) remains constant. Though, for non-Newtonian fluids, viscosity is a function of shear rate and shear stress or varies at various shear rates. Non-Newtonian fluids are: Time-dependent, Time-independent and Viscoelastic [30], [31].

1) Time-dependent: which is at constant shear rates, the viscosity of fluids modifies by time. By increasing the shear rate in these types of fluids, If the viscosity increases with time, the fluids are rheopectic and if decreases with time, they are called thixotropic.

2) Time-independent: which has no memory of their past history or not dependent on the time of applying the shear rate. In Time-independent category, Bingham fluids have initial yield stress (need initial tension to flow) [32].

3) Viscoelastic fluids: which exhibit both viscous and elastic characteristics, after undergoing deformation can be converted into the initial state.

Figure 14, shows nanofluid viscosity and shear stress by shear rate for mass fractions 1.0 to 3.5 mg/ml and temperatures 25 to 50°C. This figure shows that the rheological behavior of nanofluid is non-Newtonian. As mentioned above, non-Newtonian fluid type divided into Time-dependent and Time-independent (which divided into Shear-thinning and Shear-thickening) [33]. For Graphene Oxide, power (in power law equation) is less than one and so, pseudoplastic type (Shear-thinning) happened [34]. Equation (05) for power law is:

$$\tau = m \dot{\gamma}^n \quad (05)$$

Where τ is shear stress (Pa), $\dot{\gamma}$ is shear rate (s^{-1}), m is flow consistency index ($Pa \cdot s^n$), and n is the power-law index (dimensionless).

Also, obvious viscosity is calculated from Equation (06) as:

$$\mu = m \dot{\gamma}^{n-1} \quad (06)$$

where μ stands for obvious nanofluid viscosity [35].

It can be seen the trend of viscosity or shear stress by shear rate is non-linear. m and n values at any mass fraction and temperature can be calculated by using Equation (07) and curve-fitting method.

$$\tau = \mu \dot{\gamma} \quad (07)$$

Figure 14. Viscosity and Shear stress variations for (a) 1.0 mg/ml, (b) 1.5 mg/ml, (c) 2.0 mg/ml, (d) 2.5 mg/ml and (e) 3.5 mg/ml by shear rate

By considering nanofluid's non-Newtonian behavior, and results of Figure 14, m and n parameters obtained in Figure 15. As can be seen, Figure 15.a shows the consistency index (m). For each mass fraction, by increasing the temperature, m decreased, however in general view, by increasing mass fraction, m increased [36]. Also, Figure 15.b shows the power law index (n). For each mass fraction, by increasing temperature, n increased, however in general view, by increasing mass fraction, n decreased [37]. This behavior is logical due to decrement of viscosity by increasing temperature which causes nanofluid acts more likely to water basefluid (which has Newtonian behavior).

Figure 15. Variations in (a) Consistency index and (b) power-law index by temperature

3.3. Numerical Study

Proposed Correlation

A new correlation to calculate viscosity of Graphene-Water nanofluid offered by using a curve-fitting method (Equations 08 and 09). R² for this correlation was about 0.99 [38]. Figure 16 shows the 3D fitted equation on experimental data for both 12.23 and 122.3 shear rates.

R² for shear rate 12.23 (10 RPM) is 0.9966 and its correlation reported as:

$$\text{Vis}=[1.39544 * T^{-0.78823}] * [wt^{1.02734}] \quad (08)$$

R² for shear rate 122.3 (100 RPM) is 0.9993 and its correlation reported as:

$$\text{Vis}=[1.05301 * T^{-0.55613}] * [wt^{0.46584}] \quad (09)$$

Where viscosity is in centipoise, T stands for temperature in Celsius and wt is mass fraction [39].

Figure 16. Verify presented correlation by experimental results; viscosity by temperature and mass fraction of nanofluid for a) 10 RPM and b) 100 RPM

To verify the presented correlation by experimental data of viscosity, Equation 10 used to compute deviation. Figure 17 shows the highest deviation of margin calculated 1.88% (for RPM= 10) and 0.56% (for RPM= 100), shows that proposed correlation is valid and has high accuracy [40].

$$\text{Dev} = \left[\frac{\mu_{\text{Exp}} - \mu_{\text{Pred}}}{\mu_{\text{Pred}}} \right] * 100 \quad (10)$$

Figure 17. Verify presented correlation by experimental results for a) 10 RPM and b) 100 RPM

Artificial Neural Network

This paper aims to model the viscosity of Graphene Oxide. This model has three inputs namely the temperature, mass fraction and shear rate and also, one output namely the viscosity. To that end, an Artificial Neural Network (ANN) model is utilized. The ANN has one hidden layer and one output layer. The hidden layer has 16 sigmoid neurons while the output layer has a linear transfer function. The architecture of the ANN is illustrated in Figure 18. The Bayesian regularization backpropagation is employed as the training algorithm.

Figure 18. The architecture of the ANN

There are two training datasets for the shear rates of 12.23 (1/s) and 122.3 (1/s). Every training dataset has 36 samples obtained by the experiment. The training datasets for the investigated shear rates are illustrated in Figure 19 [41,42].

(a)

Figure 19. The training dataset for shear rates of (a) 12.23 (1/s) and (b) 122.3 (1/s)

The regression plots for the ANN model is illustrated in Figure 20. In this diagram, the numerical viscosity predicted by the ANN model is plotted against the experimental viscosity. In an ideal case, the numerical and experimental viscosities should be identical. In other words, the slope, and bias values of the fitted line should equal to 1 and 0, respectively. Hence, ANN model provides an acceptable model because the slope and bias values of the fitted regression plot are 0.997, 0.004, respectively. Moreover, the regression value is 0.9996 that indicates a suitable regression fit.

Figure 20. The regression plots for the ANN model

The prediction error of the ANN model is illustrated in Figure 21. In this figure, the error percentages are plotted against the experimental viscosity. It can be seen that the maximum error percentage is about 6% while the error percentages are generally less than 3%. Also, the error histogram illustrated in Figure 22. shows the error distribution.

Figure 21. The prediction error of the ANN model

Figure 22. The error histogram

Once the ANN model is obtained, the viscosity can be predicted in the investigated domain of the temperature, mass fraction and shear rate. Figure 23. shows the numerical viscosities predicted by the ANN model as contours. Every contour displays the viscosity as a function of the temperature and mass fraction **at** a constant shear rate. It can be observed that the shear rate severely effects the predicted viscosity. The higher the shear rate, the lower the predicted viscosity. Also, it can be seen that the viscosity increases with mass fraction while it decreases with the temperature. However, the mass fraction is more effective on the predicted viscosity than the temperature. Since the numerical values of the viscosity are obtained in non-trained shear rates, temperatures and mass fractions, the ANN is successful in **the** prediction of the nanofluid behaviors.

Figure 23. The numerical viscosities predicted by the ANN model in the investigated domain of outputs (the higher the shear rate, the lower the predicted viscosity)

4. Conclusion

In this study, dynamic viscosity of Graphene Oxide-Water nanofluid at mass fractions of 1.0 to 3.5mg/ml and temperature ranges of 25 to 50°C measured. Water has Newtonian behavior; however, when GO added to basefluid, nanofluid showed non-Newtonian behavior [43]. Viscosity increases by increasing mass fraction and decreases by increasing temperature. Nanofluid followed a power-law model. Power law model indices (m and n) found for all mass fractions and temperatures. By experimental results and curve-fitting, a correlation which shows very high accuracy, for both 12.23 and 122.3 shear rates calculated [44]. Then, correlation validated and 1.88% (for RPM= 10) and 0.56% (for RPM= 100) deviation reported [45]. A list of results listed as:

- GO, a 2D material, synthesized via modified hummers' method and then, a stable and homogeneous nanofluid has been prepared.

- By adding GO, basefluid viscosity increased and pseudoplastic behaviour reported due to the study of shear rate by shear stress.
- Zeta potential test revealed GO-water acceptable stability of nanofluid.
- Correlation presented in this paper, has the R-Squared (deviation) of about 0.99. Thus, it can calculate GO-Water viscosity in further researches.
- ANN modeled in this paper, has the R-Squared (deviation) of about 0.997. Thus, it can predict viscosity of other mass fractions and temperatures.

Conflicts of Interest

There is no conflict of interest.
