Preliminary validation of column-averaged volume mixing ratios of carbon dioxide and methane retrieved from GOSAT short-wavelength infrared spectra

Abstract
Column-averaged volume mixing ratios of carbon dioxide and methane retrieved from the Greenhouse gases Observing SATellite (GOSAT) Short-Wavelength InfraRed observation (GOSAT SWIR XCO2 and XCH4) were compared with the reference data obtained by ground-based high-resolution Fourier Transform Spectrometers (g-b FTSs) participating in the Total Carbon Column Observing Network (TCCON). Through calibrations of g-b FTSs with airborne in-situ measurements, the uncertainty of XCO2 and XCH4 associated with the g-b FTS was determined to be 0.8 ppm (0.2%) and 4 ppb (0.2%), respectively. The GOSAT products are validated with 10 these calibrated g-b FTS data. Preliminary results are as follows: The GOSAT SWIR XCO2 and XCH4 (Version 01.xx) are biased low by 8.85±4.75 ppm (2.3±1.2%) and 20.4±18.9 ppb (1.2±1.1%), respectively. The precision of the GOSAT SWIR XCO2 and XCH4 is considered to be about 1%. The latitudinal distributions of zonal means of the GOSAT SWIR XCO2 and XCH4 show similar features to those of the g-b FTS data.

Abstract

Column-averaged volume mixing ratios of carbon dioxide and methane retrieved from the Greenhouse gases Observing SATellite (GOSAT) Short-Wavelength InfraRed observation (GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$) were compared with the reference data obtained by ground-based high-resolution Fourier Transform Spectrometers (g-b FTSs) participating in the Total Carbon Column Observing Network (TCCON).

Through calibrations of g-b FTSs with airborne in-situ measurements, the uncertainty of $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ associated with the g-b FTS was determined to be 0.8 ppm (~0.2%) and 4 ppb (~0.2%), respectively. The GOSAT products are validated with these calibrated g-b FTS data. Preliminary results are as follows: The GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ (Version 01.xx) are biased low by $8.85 \pm 4.75$ ppm (2.3 ± 1.2%) and $20.4 \pm 18.9$ ppb (1.2 ± 1.1%), respectively. The precision of the GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ is considered to be about 1%. The latitudinal distributions of zonal means of the GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ show similar features to those of the g-b FTS data.

1 Introduction

The concentration of carbon dioxide ($\text{CO}_2$) has increased from about 280 to 380 ppm over the past century due to the burning of fossil fuels associated with expanding industrial activities (IPCC, 2007). $\text{CO}_2$ absorbs the infrared radiation from the surface and hence an increase in the $\text{CO}_2$ concentration leads to a rise in atmospheric temperature. $\text{CO}_2$ and other trace gases such as methane ($\text{CH}_4$), nitrous oxide ($\text{N}_2\text{O}$), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulfur hexafluoride ($\text{SF}_6$) are greenhouse gases that are subject to emission regulations under the Kyoto Protocol. Together, $\text{CO}_2$ and $\text{CH}_4$ account for over 80 percent of the total warming effect caused by all greenhouse gases based on the estimates of radiative forcing from 1750 to 2005 (IPCC, 2007). Changes in temperature can cause feedbacks that alter $\text{CO}_2$ concentrations by influencing the biosphere (Cox et al., 2000). To accurately predict future atmospheric $\text{CO}_2$ concentrations and their impacts on climate, it is necessary to clarify the distribution and variability of $\text{CO}_2$ and its sources and sinks.

Current estimates of $\text{CO}_2$ flux from inverse methods rely mainly on ground-based data (Baker et al., 2006). Errors in the estimation of regional fluxes from Africa and South America are particularly large because ground-based monitoring stations are sparsely located in those regions. Spectroscopic remote sensing from space is capable of acquiring data that cover the globe and hence is expected to reduce errors in the $\text{CO}_2$ flux estimation using inverse modeling. To improve annual flux estimates on a sub-continental scale, the required precision of monthly averaged column-averaged volume mixing ratio of carbon dioxide ($X_{\text{CO}_2}$) is less than 1% on a 8° × 10° grid without biases (Rayner and O’Brien, 2001; Houweling et al., 2004; Miller et al., 2007). For this purpose, satellite-based data products must be validated by higher-precision data obtained independently using ground-based or aircraft measurements (Chahine et al., 2005; Sussmann et al., 2005; Dils et al., 2006; Schneising et al., 2008; Kulawik et al., 2010).

In this study, the Greenhouse gases Observing SATellite (GOSAT) data products retrieved by the National Institute for Environmental Studies (NIES) are compared with ground-based high resolution Fourier Transform Spectrometer (g-b FTS) data calibrated to the World Meteorological Organization (WMO) scale. In Sect. 2, we present an overview of the GOSAT project, GOSAT instruments and observations, and retrievals from the GOSAT Thermal And Near-infrared Sensor for carbon Observation Fourier Transform Spectrometer, measuring in the Short-Wavelength InfraRed (TANSO-FTS SWIR). Reference data measured with g-b FTS are described in Sect. 3. Finally, characteristics of GOSAT SWIR products and preliminary results compared with the reference data are presented in Sect. 4.
2 Overview of GOSAT, the GOSAT instruments, and data products retrieved from GOSAT TANSO-FTS SWIR observations

2.1 GOSAT

The Greenhouse Gases Observing Satellite “IBUKI” (GOSAT), launched on 23 January 2009, is the world's first satellite dedicated to measuring the atmospheric concentrations of CO$_2$ and CH$_4$ from space. The GOSAT Project is a joint effort of the Ministry of the Environment (MOE), the National Institute for Environmental Studies (NIES), and the Japan Aerospace Exploration Agency (JAXA). NIES is responsible for (1) developing the retrieval of greenhouse gas concentrations (Level 2 products) from satellite and auxiliary data, (2) validating the retrieved greenhouse gas concentrations, and (3) producing higher-level processing such as monthly averaged $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ (Level 3 products) and Level 4 carbon flux estimates. The primary purpose of the GOSAT is to make more accurate estimates of these fluxes on sub-continental scales (several thousand square kilometers) and contributing toward the broader effort of environmental monitoring of ecosystem carbon balance. Further, through research using the GOSAT product, new knowledge will be accumulated on the global distribution of greenhouse gases and their temporal variations, as well as the global carbon cycle and its influence on climate. These new findings will be utilized to improve predictions of future climate change and its impacts.

2.2 GOSAT instruments and observation methods

Details of the GOSAT instruments have been described by Kuze et al. (2009). GOSAT is placed in a sun-synchronous orbit with an equator crossing time of about 13:00 LT (local time), with an inclination angle of 98 degrees. GOSAT flies at an altitude of approximately 666 km and completes an orbit in about 100 min. The spacecraft returns to observe the same point on Earth every three days. The instruments onboard the satellite are TANSO-FTS and the TANSO Cloud and Aerosol Imager (TANSO-CAI).

TANSO-FTS has a Michelson interferometer that was custom designed and built by ABB-Bomem, Quebec, Canada. Spectra are obtained in four bands: band 1 spanning 0.758–0.775 µm (12 900–13 200 cm$^{-1}$) with 0.37 cm$^{-1}$ or better spectral resolution, and bands 2–4, spanning 1.56–1.72, 1.92–2.08, and 5.56–14.3 µm (5800–6400, 4800–5200, and 700–1800 cm$^{-1}$, respectively) with 0.26 cm$^{-1}$ or better spectral resolution. The TANSO-FTS instantaneous field of view is $\sim$15.8 mrad corresponding to a nadir footprint diameter of about 10.5 km at sea level. The nominal single-scan data acquisition time is 4 s.

TANSO-FTS observes solar light reflected from the earth's surface as well as the thermal radiance emitted from the atmosphere and the surface. The former (SWIR region) is observed in bands 1 to 3 of the FTS in the daytime only, and the latter (Thermal Infrared, TIR, region) is captured in band 4 during both the day and the night. The surface reflection characteristics of land and water differ significantly. The land is close to Lambertian, whereas the ocean is much more specular. TANSO-FTS observes scattered sunlight over land using a nadir-viewing observation mode, and over ocean using a sunglint observation mode.

TANSO-CAI is a radiometer and observes the state of the atmosphere and the surface during daytime. The image data from CAI are used to determine cloud properties over an extended area that includes the FTS' field of view as described by Ishida and Nakajima (2009). As part of the retrieval, cloud characteristics and aerosol amounts are also retrieved. This information can be used to reject cloudy scenes and correct the influence of aerosols on the retrieved $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$.

Over the three-day orbital repeat period, TANSO-FTS takes several tens of thousands of observations that cover the globe. Since the retrievals are limited to areas under clear sky conditions, only about ten percent of the spectra obtained by TANSO-FTS can be used for the retrieval of CO$_2$ and CH$_4$. Nevertheless, the number of remaining data points far surpasses the current number of ground monitoring stations.
used for analysis in the World Data Center for Greenhouse Gases (WDCGG), which is below 200 (WMO, 2009). GOSAT serves to fill in the blanks in the ground observation network.

2.3 Products retrieved from GOSAT TANSO-FTS SWIR spectra

The analysis of the TANSO-FTS SWIR spectra is described in detail by Yoshida et al. (2010). Briefly, absorption spectra are used together to retrieve CO\textsubscript{2} and CH\textsubscript{4} column abundances. From all spectra observed with TANSO-FTS SWIR, only those measured without cloud interference are selected for further processing. Based on the absorption characteristics of each gas, the selected spectra are used to retrieve column abundances of CO\textsubscript{2} and CH\textsubscript{4} (Level 2 product). Variations in the CO\textsubscript{2} concentration are most obvious near the surface of the earth. The CO\textsubscript{2} absorption bands near 1.6 \mu m and 2.0 \mu m provide information on the near-surface concentrations. The absorption band around 14 \mu m is used to obtain information on the profiles of CO\textsubscript{2} and CH\textsubscript{4}, mainly at altitudes above 2 km (Saitoh et al., 2009).

Validation of the TANSO-FTS SWIR Level 2 data product is critical since the data are used for generating Level 3 and Level 4 products. GOSAT Level 2 products are evaluated against high-precision data obtained independently using ground-based or aircraft observations. Here we compare the GOSAT SWIR X\textsubscript{CO2} and X\textsubscript{CH4} results with those data obtained with ground-based high-resolution FTSs (g-b FTSs).

3 Reference data measured with g-b FTSs for GOSAT product validation

3.1 X\textsubscript{CO2} and X\textsubscript{CH4} retrieval from spectra measured with g-b FTSs

Spectra measured with g-b FTS are analyzed using the GFIT nonlinear least squares spectral fitting algorithm developed at the Jet Propulsion Laboratory (Toon et al., 1992; Wunch et al., 2010b), which is used for retrievals across all stations that comprise the Total Carbon Column Observing Network (TCCON; Wunch et al., 2010b). Here, we use the GFIT 7 March 2009 release.

The column-averaged volume mixing ratio of CO\textsubscript{2} (X\textsubscript{CO2}) is defined to be the ratio of the CO\textsubscript{2} column amount to the dry air column amount. To calculate the dry air column, we use the measured O\textsubscript{2} column, divided by the known dry air mole fraction of O\textsubscript{2} (0.2095). The O\textsubscript{2} column is measured simultaneously with the CO\textsubscript{2} column using the spectral band covering 1.25–1.29 \mu m. X\textsubscript{CO2} is obtained from:

\[
X_{\text{CO2}} = 0.2095 \left( \frac{\text{CO}_2 \text{ column}}{\text{O}_2 \text{ column}} \right)
\]

Ratioring by O\textsubscript{2} minimizes systematic and correlated errors present in both retrieved columns like pointing error, surface pressure uncertainty, instrument line shape uncertainty, H\textsubscript{2}O vapor uncertainty, zero level offsets and solar intensity variation (e.g. thin clouds).

The precision of g-b FTS measurement of X\textsubscript{CO2} is better than 0.2% under clear sky conditions (Washenfelder et al., 2006; Ohyama et al., 2009; Wunch et al., 2010b; Messerschmidt et al., 2010). All TCCON X\textsubscript{CO2} data are corrected for an airmass-dependent artifact (Wunch et al., 2010b). Aircraft profiles obtained over many of these sites are used to determine an empirical scaling to place the TCCON data on the WMO standard reference scale. The scaling factors of X\textsubscript{CO2} and X\textsubscript{CH4} are 1.011 and 1.022, respectively. The uncertainty of X\textsubscript{CO2} and X\textsubscript{CH4} associated with the g-b FTS measurement is estimated to be 0.8 ppm (~0.2%) and 4 ppb (~0.2%) by comparing the TCCON retrievals with many different aircraft profiles (Wunch et al., 2010a).

3.2 FTS sites used for validation

The g-b FTS data at 9 sites are used in this analysis. Figure 1 shows the location of the FTS sites which are used in the present study. FTS sites are located in Asia, Oceania, Europe, and North America. Table 1 summarizes the spatial coordinates of those stations.
4 Results of initial validation

4.1 GOSAT product selection for validation

The GOSAT SWIR $X_{CO2}$ and $X_{CH4}$ products used here are Ver.01.xx. The retrieval algorithm for Ver.01.xx uses band 1 (12 900–13 200 cm$^{-1}$) and band 2 (5800–6400 cm$^{-1}$) to simultaneously estimate $X_{CO2}$ and $X_{CH4}$. In addition, the water vapor profile and aerosol optical depth (AOD) at a wavelength of 1.6 µm are retrieved. Band 3 is used for selecting scenes with cirrus clouds which CAI can not detect (Yoshida et al., 2010). The $X_{CO2}$ and $X_{CH4}$ data shown here (general public users, or GU subset) are filtered for AOD less than 0.5. As a plane-parallel atmosphere is assumed in the retrieval, data with solar zenith angles greater than 70° are not processed, and data over high mountain ranges such as the Rockies, the Andes, and the Himalayan mountains are removed.

4.2 Global distribution of $X_{CO2}$ and $X_{CH4}$

Figures 2 and 3 show the global distribution of GOSAT SWIR $X_{CO2}$ and $X_{CH4}$ measured in April and October 2009. When several GOSAT data were retrieved at the same observation point in the month, the latest retrieved value was overwritten in Figs. 2 and 3. There are retrievals that satisfy the filter criteria over North Africa, the Arabian Peninsula, and Australia. Data over land are obtained mainly for 10–60° N and 15–45° S in April, and 10–50° N and 0–50° S in October. Data over ocean are retrieved in the regions of 10° S–30° N in April and 40° S–10° N in October by observing the specular reflection of sunlight in the direction of sunglint. $X_{CO2}$ in April is generally higher in the Northern Hemisphere than the Southern Hemisphere (Fig. 2). This is because plant photosynthesis in the Northern Hemisphere is not yet competitive with respiration in April. In October, similar $X_{CO2}$ is observed in both hemispheres. The standard deviations of monthly mean $X_{CO2}$ is about 1% for a $10^\circ \times 10^\circ$ grid over Australia, where gradients are anticipated to be very small.

$X_{CH4}$ in the Northern Hemisphere is higher than in the Southern Hemisphere in both April and October 2009 (Fig. 3). Elevated $X_{CH4}$ is observed from India to Japan in October 2009. These features are similar to those obtained by SCIAMACHY (Frankenberg et al., 2006) and simulated by an inversion model (Bergamaschi et al., 2007).

4.3 Comparisons between g-b FTS data and GOSAT TANSO-FTS SWIR data

GOSAT TANSO-FTS SWIR data are compared with the g-b FTS data at 9 TCCON sites (Fig. 1). We illustrate here the time series of the TANSO-FTS SWIR Level 2 data and g-b FTS data and their scatter diagrams for $X_{CO2}$ and $X_{CH4}$. The g-b FTS data are the mean values and standard deviations (one sigma) measured at each FTS site within 30 min of GOSAT overpass time (at most sites, around 13:00 LT). The GOSAT data are selected within about one to three degrees rectangular area centered at each FTS site depending on the geophysical distribution of land and sea. As much as possible, we used only the GOSAT data retrieved over flat land.

4.3.1 $X_{CO2}$

The time series of the GOSAT and g-b FTS data for $X_{CO2}$ are shown on the left and their scatter diagram on the right in Figs. 4 and 5g,h. In the scatter diagram, we plotted data when g-b FTS data were collected within 30 min of the GOSAT overpass time and corresponding GOSAT $X_{CO2}$ values were successfully retrieved. Only a few GOSAT data are available for comparison with Bialystok, Garmisch, Park Falls and Lauder. Darwin FTS data were not obtained since 2010 due to mechanical problems with the sun tracker. $X_{CO2}$ retrieved from GOSAT SWIR measured near Orleans, Lamont and Tsukuba sites are higher in boreal spring and lower in autumn (Figs. 4b, 5e and f). Although GOSAT data are generally biased low compared with the g-b FTS, similar seasonal variations are observed. A clear seasonality over the Northern Hemisphere can also be seen in the horizontal maps of Fig. 2. In contrast, the seasonal variation...
of g-b FTS $X_{\text{CO}_2}$ in the Southern Hemisphere (i.e., Darwin, Wollongong, and Lauder) is weak (Fig. 5g,h and i) as expected due to smaller contribution of the continents.

Figure 6 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites, and Table 2 summarizes the difference of the GOSAT data to the g-b FTS data at each site. The difference of the GOSAT data to the g-b FTS data is $-8.85 \pm 4.75$ ppm or $-2.3 \pm 1.2\%$.

### 4.3.2 $X_{\text{CH}_4}$

The time series of the GOSAT and g-b FTS data for $X_{\text{CH}_4}$ are shown on the left and their scatter diagrams on the right in Figs. 7 and 8. The GOSAT retrievals are quite similar to the g-b FTS data for each site. Furthermore, the bias of $X_{\text{CH}_4}$ is smaller than that of $X_{\text{CO}_2}$. In Lamont and Orleans, $X_{\text{CH}_4}$ levels obtained from GOSAT SWIR are higher in boreal autumn. The g-b FTS data of $X_{\text{CH}_4}$ over Tsukuba have a peak in summer rather than autumn.

Figure 9 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites. The difference of the GOSAT data to the g-b FTS data at each site is shown in Table 3. The difference of the GOSAT data to the g-b FTS data is $-20.4 \pm 18.9$ ppb or $-1.2 \pm 1.1\%$.

### 4.4 Latitudinal distributions of zonal averaged GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$

In Sect. 4.3, g-b FTS data recorded within 30 min of the GOSAT overpass were used for the validation. To obtain larger number of samples and depict the latitudinal features, we calculated monthly mean $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ of g-b FTS data obtained within 30 min of the time when GOSAT is supposed to overpass for all days, including the days when GOSAT does not overpass each site. In addition, monthly mean values of zonal averaged GOSAT data, based on all data obtained, are calculated in each 15 degree latitudinal band.

Latitudinal distributions of monthly means of zonal averaged GOSAT SWIR and g-b FTS data of $X_{\text{CO}_2}$ in April and October 2009 are shown in Fig. 10. Both data sets show that $X_{\text{CO}_2}$ is higher in the Northern Hemisphere compared with the Southern Hemisphere in April and the difference between the hemispheres is small in October. The difference of $X_{\text{CO}_2}$ between April and October is about 5 ppm in the northern mid latitudes for both data sets. The zonal means of GOSAT data are reasonably consistent with those of the reference values.

Figure 11 shows latitudinal distributions of monthly means of zonal averaged GOSAT SWIR and g-b FTS data of $X_{\text{CH}_4}$ for April and October 2009. $X_{\text{CH}_4}$ is characterized by relatively high concentration in the Northern Hemisphere in April and October. Moreover, the bias is smaller than that of $X_{\text{CO}_2}$. In particular, concentration of $X_{\text{CH}_4}$ of GOSAT data is a good agreement with that of g-b FTS sites in April. Both $X_{\text{CH}_4}$ data in October are similar distribution, though a striking difference is seen near 50–60° N.

### 5 Discussion

In this study, we performed the validation of GOSAT TANSO-FTS SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$. In Ver.01.xx, the influence of aerosols has been markedly reduced compared with earlier versions of the retrievals (Yokota et al., 2009). However, bias due to aerosols and thin cirrus clouds still exists because the anomalously low $X_{\text{CO}_2}$ retrievals as illustrated in Fig. 2. In the future, we plan to investigate interferences by aerosols and thin cirrus clouds using aerosol lidars and/or sky-radiometers at selected FTS sites.

The negative bias of about 9 ppm or 2.3% in the GOSAT TANSO-FTS SWIR data of $X_{\text{CO}_2}$ is not still understood. It may result from unknown spectroscopic parameters of O$_2$ and CO$_2$ or error in the TANSO-FTS calibration. In the case of the GOSAT SWIR data of $X_{\text{CH}_4}$, the negative bias decreased in the Ver.01.xx compared with the earlier Ver.00.yy when the spectroscopic parameters were changed from Lyulin et al. (2009) to HITRAN 2008 database (Rothman et al., 2009).
The precision of the GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ is considered to be about 1%. The retrieval errors of $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ are on average 2 ppm and 8 ppb or about 0.5% respectively. The retrieval errors include TANSO-FTS SWIR measurement noise, smoothing error and interference error, and the main error is the measurement noise (Yoshida et al., 2010). This means that the other errors of about 0.5% are due to influences of factors such as aerosols and thin cirrus clouds.

6 Conclusions

The GOSAT TANSO-FTS SWIR data of $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ in the Version 01.xx were compared against reference data obtained with the TCCON g-b FTS sites. The GOSAT TANSO-FTS SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ were biased low by $8.85 \pm 4.75$ ppm (2.3 $\pm$ 1.2%) and $20.4 \pm 18.9$ ppb (1.2 $\pm$ 1.1%) respectively than the reference values. The precision of the GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ retrievals is considered to be about 1%.

Although $X_{\text{CO}_2}$ is underestimated by approximately 9 ppm, the GOSAT retrievals and g-b FTS data show similar seasonal behaviors over the Northern Hemisphere, higher in spring and lower in autumn. The latitudinal distribution of zonal averaged GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ is broadly consistent with that of the g-b FTS. We plan further study to address the negative bias of the GOSAT SWIR $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ as well as to better understand the influence of aerosols and thin cirrus clouds.

Acknowledgements. We express our sincere thanks to the members of the NIES GOSAT project office, data algorithm team, atmospheric transport modeling team for their useful comments. We thank Nobuyuki Kikuchi in NIES and Komei Yamaguchi in the Japan Weather Association for plotting the data. This work was funded by the Ministry of the Environment in Japan. We also thank NASA’s Terrestrial Ecology Program and the Orbiting Carbon Observatory for their support of TCCON, and acknowledge support from the EU within the projects GEOMON and IMECC. The Lauder TCCON measurements are funded by New Zealand Foundation for Research, Science and Technology contracts CO1X0204 and CO1X0406.

Table 2. Left side: the average and one standard deviation ($1 \sigma$) of the difference between GOSAT $X_{\text{CO}_2}$ and g-b FTS $X_{\text{CO}_2}$ for the nine TCCON sites. Right side: the average and one standard deviation ($1 \sigma$) of the difference normalized to g-b FTS $X_{\text{CO}_2}$ (given in percent). Note that the number of data listed here indicates the count of valid cases in which g-b FTS data were collected within 30 min of the GOSAT overpass time and corresponding GOSAT $X_{\text{CO}_2}$ values were successfully retrieved.

Fig. 1. Ground-based FTS sites used for the GOSAT product validation in the present study.

Fig. 2. Global distribution of GOSAT SWIR $X_{CO2}$ for (a) April and (b) October in 2009.
Fig. 3. Global distribution of GOSAT SWIR $X_{\text{CH}_4}$ for (a) April and (b) October in 2009.

Fig. 4. Time series of GOSAT TANSO-FTS SWIR (blue triangles) and g-b FTS (pink squares) $X_{\text{CO}_2}$ and their scatter diagram for (a) Bialystok, (b) Orleans, (c) Garmisch, and (d) Park Falls.
**Fig. 5.** As in Fig. 4 except for (e) Lamont, (f) Tsukuba, (g) Darwin, (h) Wollongong, and (i) Lauder.

**Fig. 6.** Scatter diagram between GOSAT TANSO-FTS SWIR and g-b FTS $X_{CO2}$ at FTS sites.
Fig. 7. Time series of GOSAT TANSO-FTS SWIR (blue triangles) and g-b FTS (pink squares) $X_{\text{CH}_4}$ data and their scatter diagram for (a) Bialystok, (b) Orleans, (c) Garmisch, and (d) Park Falls.

Fig. 8. As in Fig. 7 except for (e) Lamont, (f) Tsukuba, (g) Darwin, (h) Wollongong, and (i) Lauder.
Fig. 9. Scatter diagram between GOSAT TANSO-FTS SWIR and g-b FTS $X_{\text{CH}_4}$ at FTS sites.

Fig. 10. Latitudinal distributions of monthly means of zonal averaged GOSAT $X_{\text{CO}_2}$ for each 15 latitudinal band in April and October 2009 (blue triangles). The monthly means of g-b FTS data observed during local time of about 12:30–13:30 h are shown by pink squares. Vertical bars indicate the standard deviation.
Fig. 11. As Fig. 10 but for $X_{\text{CH}_4}$.
