Controllable ring signatures and its application to E-prosecution

Abstract
This paper introduces a new concept called controllable ring signature which is ring signature with additional properties as follow. (1) Anonymous identification: by an anonymous identification protocol, the real signer can anonymously prove his authorship of the ring signature to the verifier. And this proof is non-transferable. (2) Linkable signature: the real signer can generate an anonymous signature such that every one can verify whether both this anonymous signature and the ring signature are generated by the same anonymous signer. (3) Convertibility: the real signer can convert a ring signature into an ordinary signature by revealing the secret information about the ring signature. These additional properties can fully ensure the interests of the real signer. Especially, compared with a standard ring signature, a controllable ring signature is more suitable for the classic application of leaking secrets. We construct a controllable ring signature scheme which is provably secure according to the formal definition. As an application, we design a E-prosecution scheme based on this controllable ring signature scheme and show its security. 2013 ACADEMY PUBLISHER.

Abstract—This paper introduces a new concept called controllable ring signature which is ring signature with additional properties as follow. (1) Anonymous identification: by an anonymous identification protocol, the real signer can anonymously prove his authorship of the ring signature to the verifier. And this proof is non-transferable. (2) Linkable signature: the real signer can generate an anonymous signature such that every one can verify whether both this anonymous signature and the ring signature are generated by the same anonymous signer. (3) Convertibility: the real signer can convert a ring signature into an ordinary signature by revealing the secret information about the ring signature. These additional properties can fully ensure the interests of the real signer. Especially, compared with a standard ring signature, a controllable ring signature is more suitable for the classic application of leaking secrets. We construct a controllable ring signature scheme and show its security.

Index Terms—Certificateless cryptography; certificateless threshold decryption; provable security; random oracle model; bilinear pairing

I. INTRODUCTION

The concept of ring signatures was introduced by Rivest, Shamir and Tauman in [2]. It enables any individual to spontaneously conscript arbitrarily \( n - 1 \) entities and generate a publicly verifiable 1-out-of-\( n \) signature on behalf of the whole group (called a ring), yet the actual signer remains anonymous. Many extensions of a standard ring signature, such as linkable ring signature [3], convertible ring signature [4], separable ring signature [5], [6], threshold ring signature [7], ID-based ring signature [8], proxy ring signature [9], ring authenticated encryption [10], conditionally anonymous ringsignature [11] have been proposed in the literature. Ring signature and its variants have been used in many applications such as leaking secrets [2], designated verifier signature [2], anonymous identification/authentication for ad hoc groups [7], e-voting [3], e-cash, attestation in [12], bidder-anonymous english auction [13] and so on.

For the motivation of our new concept, we revisit the classic application of ring signatures in leaking secrets. Suppose that Bob (also known as “Deep Throat”) is a member of the cabinet of Lower Kryptonia, and that Bob wishes to leak a juicy fact to a journalist about the escapades of the Prime Minister, in such a way that Bob prevents this impersonation? Suppose that the journalist is very interested in these leaked secrets and wants to communicate with the real signer in order to discuss more details. So the journalist publishes his telephone number and wants the real signer to contact him through an anonymous

phone call. How can Bob convince the journalist that the anonymous call is from the real signer through a untransferable proof?

(3) Suppose that Bob needs to publish further proofs for the escades of the Prime Minister. How can Bob make people believe that both the previous secrets and these further proofs are leaked by the same anonymous cabinet member?

(4) After the disgraced Prime Minister is disposed, Bob maybe wants to remove the anonymity of the ring signature. In other words, how can Bob convert the ring signature into a standard digital signature?

Roughly speaking, (2) motivate the topic of secure anonymous identification; (3) can be captured by the notion of the linkability of anonymous signatures; (4) can be formalized as the notion of convertibility of a ring signature.

A. Related Work

Some extensions of a standard ring signature can only partially solve the above mentioned problems. In fact, the above problems were not so comprehensively pointed out in existing literature. Now we briefly review these related work.

Linkable ring signatures proposed in [3] have some limitations for leaking secrets. First, the schemes in [3] are not unconditionally but computationally anonymous. Secondly, every one can deny a ring signature if he is not the real signer. Thirdly, the real signer can’t deny the ring signature generated by himself. In fact, in [3], the linkability of a ring signature was proposed mainly for restricting the real signer. For example, a linkable ring signature can prevent a ring member from generating two ring signatures on the message in the applications such as E-cash and E-voting. On the contrary, in the application of leaking secrets, the attention should be focused on how to fully ensure the interests of the real signer.

The convertible ring signature scheme proposed in [4] is the extension of a ring signature scheme proposed in [2]. It deals with only the convertibility of the ring signature. And their construction cannot be trivially extended to deal with the linkability and anonymous identification. Additionally, the authors did not formalize the security model for the convertibility of ring signatures and their analysis is too simple.

The modified ring signature in [2] can guarantee only the computational anonymity. The proposed way can be used to show that a non-signer is not the real signer. A similar way can be used to show who is the real signer. In fact, they proposed a way to convert a ring signature to an ordinary signature. However, it seems difficult to extend their way to deal with the properties of linkability and anonymous authorship of a ring signature.

B. Contributions

Our contributions are twofold, as listed below. On the one hand, we revisit the classic application of ring signatures in leaking secrets and point out a list of practical problems unsolved by a standard ring signature. Motivated by these problems, we formalize the new notion of controllable ring signature. It is a useful cryptographic primitive which can fully ensure the interests of the real signer and rightly restrict him as follows.

(1) The real signer remains unconditionally anonymous unless he himself exposes his identity.

(2) Despite the unconditional anonymity, the real signer has enough power to control his signature in the sense that he can anonymously prove his authorship, generate a linkable signature, and convert the controllable ring signature.

(3) Despite the full power to control his signature, the real signer is rightly restricted since he is not able to generate a controllable ring signature and then convince a third party that it is generated by others.

(4) Despite the unconditional anonymity, any other party (non-signer) cannot abuse the anonymity. For example, there is no way for him to present the proof that the ring signature is (or not) due to him.

On the other hand, we propose an efficient construction of a controllable ring signature, which is based on the standard ring signature of Abe et al. [6]. And the underlying paradigm may also be used to transform other standard ring signatures to controllable ones.

At last, as an application, we design an E-Prosection scheme and analyze its security.

II. FRAMEWORK AND SECURITY REQUIREMENTS

A. Syntax of Controllable Ring Signature

Definition 1 (Syntax of CRS): A controllable ring signature scheme contains eight algorithms (or protocols):
GenKey, RSign/RVerify, AIdentify, SSign/SVerify, Convert/CVerify as follows:

- GenKey: On input a security parameter 1^s, it outputs a private key sk and a public key pk.
- RSign: It takes a message m, the list, say L, of public keys \{pk_i\}_{i=0}^{n-1} of ring members \{A_i\}_{i=0}^{n-1} and the real signer A_k’s secret key sk_k, and outputs a controllable ring signature \sigma and a secret information \pi. \sigma is public and \pi is secretly stored by \Ak. We will call \{pk_i\}_{i=0}^{n-1} or \{A_i\}_{i=0}^{n-1} the ring for \sigma indiscriminately. And we will call a party not being \Ak a non-signer. If a party is in \{A_i\}_{i=0}^{n-1}, he will be called a ring member. And a party not in \{A_i\}_{i=0}^{n-1} will be called a non-member.
- RVerify: It takes the message m, the ring L, and the controllable ring signature \sigma, and outputs either 1 or 0 meaning whether \sigma is valid for m and L or not.
- AIdentify: It is a protocol between the signer \Ak and a verifier. The common inputs are the message m, the ring \{pk_i\}_{i=0}^{n-1} and the controllable ring signature \sigma for m and L generated by \Ak. It allows \Ak to anonymously prove his authorship of \sigma. We require that the verifier cannot get any information about identity of the real signer from the properties of the communication channel.
- \textbf{SSign:} It takes \( m', \pi, \sigma, \) and outputs an anonymous signature \( \sigma' \) on the message \( m' \). Here, \( \pi \) is the secret information associated with the controllable ring signature \( \sigma \). We call \( \sigma' \) a linkable signature for \( \sigma \).

- \textbf{SVerify:} It takes a message \( m' \), a controllable signature signature \( \sigma \) and a linkable signature \( \sigma' \), and outputs 1 or 0 meaning whether \( \sigma' \) and \( \sigma \) are linkable (i.e., whether \( \sigma \) and \( \sigma' \) are generated by the same anonymous ring member).

- \textbf{Convert/CVerify:} After the real signer of a controllable signature \( \sigma \) reveals the relative secret information \( \pi \) and his identity \( A_k \), every one can verify whether \( \sigma \) is generated by \( A_k \).

\section{Security Requirements of Controllable Ring Signatures}

We now describe four security requirements of a controllable ring signature scheme, which are perfect anonymity, uncontrollability, I-unforgeability, and II-unforgeability. In the following definitions, adversaries will be allowed to query some oracles: (1) A controllable ring signing oracle \( O_R \) which returns a controllable ring signature with respect to the queried message \( m \), the ring \( L \); (2) a converted ring signing oracle \( O_{C_R} \) which returns a converted ring signature with respect to the queried message \( m \), the ring \( L \) and the real signer \( A_k \); (3) an anonymously identifying oracle \( O_A \) which returns an interactive proof for proving the secret value associated with the queried controllable ring signature; (4) a linkable signing oracle \( O_S \) which returns a linkable signature on the queried message for the given controllable ring signature; (5) the corrupting oracle \( O_K \) which returns the secret key corresponding to the queried public key \( pk \).

\textbf{Definition 2 (Signer Anonymity):} Let \( L = \{ pk_0, pk_1, \ldots, pk_{n-1} \} \) where each key is generated as \( (pk_i, sk_i) \leftarrow \text{GenKey}(1^{\kappa}) \). A controllable ring signature scheme is perfectly signer-anonymous if, for any \( L \), any message \( m \), and any \( \sigma \) generated by \( R\text{Sign}(m, L, sk) \) where \( sk \) is uniformly chosen from \( \{ sk_0, sk_1, \ldots, sk_n \} \), given \( (L, m, \sigma) \), any unbound adversary \( \mathcal{A}^{O_A, O_{C_R}}(L, m, \sigma) \) outputs \( i \) such that \( sk = sk_i \) with probability exactly \( 1/|L| \).

The above property ensures that the real signer remains unconditionally anonymous even after he generates linkable signatures or anonymously proves his authorship, as long as he does not convert this controllable ring signature.

\textbf{Definition 3 (Uncontrollability against Non-Signers):} Let \( L \) be the ring \( \{ pk_0, pk_1, \ldots, pk_{n-1} \} \) where \( (pk_i, sk_i) \leftarrow \text{GenKey}(1^{\kappa}) \). Let \( \kappa = \min(\kappa_0, \ldots, \kappa_{n-1}) \). A controllable ring signature scheme is uncontrollable if, for any \( L \), any message \( m \), and any \( \sigma \) generated by \( R\text{Sign}(m, L, sk) \) where \( sk \leftarrow R \{ sk_0, sk_1, \ldots, sk_n \} \), any polynomial-time oracle machine \( \mathcal{A}^{O_A, O_{C_R}} \) succeeds only with negligible probability in \( \kappa \) for any one of the following tasks: for the ring signature \( (L, m, \sigma) \) which is not converted, he tries to generate a valid linkable signature for \( (L, m, \sigma) \), or prove the authorship, or output(\( \pi', pk' \)) such that \( \text{CVerify}(L, m, \sigma, \pi', pk') = 1 \); for the converted ring signature \( (L, m, \sigma, pk, \pi) \), he tries to output another pair (\( \pi'', pk'' \)) for \( pk'' \neq pk \) s.t. \( \text{CVerify}(L, m, \sigma, \pi'', pk'') = 1 \).

The above property ensures that a controllable ring signature cannot be controlled by any non-signer: before the controllable ring signature is converted, any non-signer cannot anonymously claim the authorship, generate a linkable signature or convert it. Furthermore, it ensures that any non-signer cannot dishonestly convert a controllable ring signature even he attains the correct converted ring signature.

\textbf{Definition 4 (I-Unforgeability against Non-Ring-Members)} Let \( (pk_i, sk_i) \) is generated by running \( \text{GenKey}(1^{\kappa}) \) for \( i = 0, \ldots, n - 1 \). Let \( \kappa = \min \{ \kappa_0, \ldots, \kappa_{n-1} \} \) and \( L = \{ pk_0, \ldots, pk_{n-1} \} \). A controllable ring signature scheme is existentially I-unforgeable against adaptive chosen-message and chosen public key attacks if, for any polynomial-time oracle machine \( \mathcal{A}^{O_{C_R}} \) such that \( (L, m, \sigma) \leftarrow \mathcal{A}^{O_{C_R}}(L) \), its output satisfies \( \text{RVerify}(L, m, \sigma) = 1 \) only with negligible probability in \( \kappa \). Restriction is that \( L \subseteq L \) and \( (L, m, \sigma) \) does not appear in the set of oracle queries and replies between \( A \) and \( O_R \).

Roughly speaking, as in a standard ring signature scheme, any controllable ring signature cannot be forged by any non-ring member. Note that the above definition is almost the same to the unforgeability defined in [6] with trivial and negligible differences.

\textbf{Definition 5 (II-Unforgeability of Converted Ring Signatures)} Let \( L = \{ pk_0, pk_1, \ldots, pk_{n-1} \} \) where each key is generated as \( (pk_i, sk_i) \leftarrow \text{GenKey}(1^{\kappa}) \). A controllable ring signature scheme is II-unforgeable against non-signers if, any polynomial time adversary \( \mathcal{A}^{O_{C_R}, O_K}(L) \) outputs \( (m, L, \sigma, \pi, pk) \) such that \( \text{CVerify}(L, m, \sigma, pk, \pi) = 1 \) with only negligible probability in \( \kappa \). Restriction is that \( \mathcal{A} \) does not get the secret key \( pk \) corresponding to \( \sigma \) from the oracle \( O_K \) and \( A \) does not get the converted ring signature \( (\sigma, \pi) \) with respect to \( (L, m, pk) \) from the oracle \( O_{C_R} \).

The above property ensures that: for a ring \( L \), even if the attacker corrupts all ring members but the single one \( A_k \) which he will attack, he can not forge the converted ring signature due to the party \( A_k \). Trivially, this property implies that the real signer is not able to dishonestly convert a ring signature into that due to the other ring member.

\section{Building Blocks and the Paradigm}

In this section, we briefly describe some cryptographic schemes that will be used to construct our controllable ring signature.

\textbf{A. Abe et al.'s Ring Signature Scheme}

\textbf{Genkey:} Let \( p_i, q_i \) be large primes. Let \( (g_i) \) denote a prime subgroup of \( \mathbb{Z}_{q_i} \) generated by \( g_i \) whose order is \( q_i \). Choose a random \( x_i \in \mathbb{Z}_{q_i} \) as the secret key and set \( y_i = g_i^{x_i} \mod p_i \). Let \( H_j : \{ 0, 1 \}^{*} \rightarrow \mathbb{Z}_{q_i} \) be publicly available hash functions. Let \( pk_i = (p_i, q_i, g_i, y_i, H_i) \) be
the DL public key of the ring member $A_i$. Let $L$ be the set \( \{ pk_i \}_{i=0}^{n-1} \).

**RSign**: $A_k$ generates a ring signature for the message $m$ and the ring $L$ as follows.

1. **Initialization**: Select $\alpha \in R \mathbb{Z}_q$, and compute $c_k = g_k^\alpha \mod p_k$. Compute $c_{k+1} = H_{k+1}(L, m, e_k)$.

2. **Forward Sequence**: For $i = k + 1, \ldots, n - 1$, select $s_i \leftarrow \mathbb{Z}_q$, and compute $c_{i+1} = H_{i+1}(L, m, g_i^{s_i}y_i^{c_i} \mod p_i)$.

3. **Forming the ring**: Compute $s_k = \alpha - c_kx_k \mod q_k$.

The resulting signature is $\sigma = (c_0, s_0, \ldots, s_{n-1}; p_0, \ldots, p_{n-1})$.

**RVerify**: A ring signature $\sigma = (c_0, s_0, \ldots, s_{n-1}; p_0, \ldots, p_{n-1})$ for the message $m$ is verified as follows. For $i = 0, \ldots, n - 1$, compute $c_i = g_i^{s_i}y_i^{c_i} \mod p_i$ and then compute $c_{i+1} = H_{i+1}(L, m, e_i)$ if $i \neq n - 1$. Accept if $c_0 = H_0(L, m, e_{n-1})$. Reject otherwise.

**B. Pedersen’s Commitment Scheme**

Pedersen’s commitment scheme [14] is as follows. Let the DL public key $(p, q, g, y)$ be generated as in the above scheme and the secret key $log_y y_i$ be generated by a trusted center. The commitment commits to $c \in \mathbb{Z}_q$ by choosing $s \in \mathbb{Z}_q$ at random and computing $E(c, s) = g^c y^s \mod p$. For $E(c, s) = g^c y^s \mod p$, $log_y y_i$ is the trapdoor: given $c, s$ and $log_y y_i$, it is easy to compute another pair $(c', s')$ such that $g^c y^s = g^{c'} y^{s'} \mod p$.

For this commitment scheme, we have the following properties:

1. (1) statistical hiding: $E(c, s)$ reveals no information about $c$; (2) computational binding: the committer cannot open a commitment to $c$ as $c' \neq c$ unless he can find $log_y y_i$; (3) trapdoor exposure: $(c, s)$ and $(c', s')$ satisfying $E(c, s) = E(c', s')$ and $(c, s) \neq (c', s')$ can be used to compute the trapdoor $log_y y_i$.

There is an honest-verifier zero-knowledge protocol for proof of knowledge of the opening $(c, s)$ for a commitment $E(c, s)$ [15]. Based on this basic protocol, it is easy to modularly construct a digital signature using the Fiat-Shamir technique [16] or to a zero-knowledge proof of knowledge of $(c, s)$ secure against cheating verifiers using the paradigm proposed in [17].

**C. A New Variant Schnorr Signature Scheme**

In this section, we will construct a special digital signature scheme by sequentially applying two modular transformations [16], [18] to the well-known Schnorr identification protocol [19]. It is obvious that the resulting signature scheme is inferior to the Schnorr signature scheme, but we claim that the purpose to propose the following scheme is not for a practical digital signature scheme but for showing the security of our proposed controllable ring signature.

Now, we present the new variant Schnorr signature scheme as follows.

1. **Key Generation**: The signer’s public key is a DL public key $pk_3 = (p_1, q_1, g_1, y_1, H_1)$ as in the above ring signature scheme. And the signing secret key is $x_k = \log_y y_1$. Additionally, the DL public key $pk_3 = (p_1, q_1, g_1, y_1, H_1)$ for the trapdoor commitment is also needed. Here, it is required that the secret key is not known by any one. In practice, such $pk_3$ can be generated as follows.

   Let $p_1$ and $q_1$ be two primes such that $q_1 | p_1 - 1$ and $q_1 \nmid p_1 - 1$ and $g_1$ be the generator of the $q$-order subgroup. $H_1 : \{ 0, 1 \}^* \rightarrow \mathbb{Z}_{p_1}$ is the cryptographic hash function. Additionally, we also need another public hash function $H'_1 : \{ 0, 1 \}^* \rightarrow \mathbb{Z}_{p_1}$. Set $y_1 = H'_1(0)^{(p_1-1)/q_1} \mod p_1$, where $l$ can be any publicly known string, e.g., $l = p_1 || q_1 || g_1$.

   Note that if $q_1 | p_1 - 1$ and $q_1 \nmid p_1 - 1$, then $r^{p_1-1} \mod p_1$ is always an element generated by $g_1$ for any $r \in \mathbb{Z}_{p_1}$. Also note that it is easy to check whether $p_1, q_1, g_1, y_1$ (with public $l$) are honestly generated. And given honestly generated $p_1, q_1, g_1, y_1$, it is infeasible for one to get $log_y y_1$.

   For simplicity, we just assume that $p_1, q_1, g_1, y_1, H_1$ are public parameters where $log_y y_1$ is not known by anyone.

2. **Signing**: Given the message $m$, first select $\alpha \in R \mathbb{Z}_q$ and compute $c = g_\alpha \mod p_1$. Then compute the Pedersen’s commitment of $c$ as $c' = g_\alpha \mod p_2$ where $r \in \mathbb{Z}_{p_2}$. Next, compute $e = H_1(m, c')$ and $s = \alpha - e \mod q_1$. The output signature is $\sigma = (c, s, r)$.

3. **Verification**: Given the signature $\sigma = (c, s, r)$ and the message $m$, check whether $c = H_1(m, g_1^{H_1(c')y_1^{c'} \mod p_1}) \mod p_1$.

We give the security analysis as follows. First, we review the two underlying paradigms for the above scheme. In [18], the Damgård’s paradigm was proposed to modularly turn a special honest-verifier zero-knowledge protocol (called $\Sigma$-protocol) into a concurrent zero-knowledge proof of knowledge in the auxiliary string model (i.e., it is assumed that the secret key for the trapdoor commitment is not known by any one except the trusted party). The Fiat-Shamir paradigm [16] is widely used to modularly construct a digital signature scheme secure in the random oracle model from a three-pass secure identification against passive attacks [20]. It is easy to see that the above scheme is constructed by sequentially applying the Damgård’s transformation and the Fiat-Shamir paradigm to the Schnorr identification protocol. The unforgeability of the digital signature can be modularly derived from the properties of the two paradigms [18], [20]. Here, we omit the straightforward and lengthy security proof from scratch. In more details, we have the following lemma which will be used to show the security of the controllable ring signature scheme:
Claim 1: If the hash function $H_1$ is assumed to be a random oracle, the other hash function $H_2$ is collision-resistant, the secret key $\log y_1$ for the commitment is not be known by anyone and the discrete logarithm problem is intractable, then the above digital signature scheme is existentially unforgeable against adaptively chosen-message attacks.

IV. PROPOSED CONTROLLABLE RING SIGNATURE SCHEME

A. Paradigm for Constructing Controllable Ring Signatures

Note that for an ordinary ring signature, although every ring member can anonymously generate a signature, he has to “close the ring” at his own position using his own secret key. If the real signer hides some proof for the “closing position” in the ring signature (in our construction, we perfectly hide the proof through Pedersen’s commitment scheme), he will be able to control it as follows. On the one hand, before the hidden proof is public, this controllable ring signature is just like a standard ring signature. And the real signer can anonymously prove his authorship, or generate linkable ring signatures by using the hidden proof as the secret key. After the hidden proof is public, this controllable ring signature is converted into a standard signature generated by the real signer.

B. The Proposed Scheme

Our scheme is the extension of the above reviewed ring signature scheme from [6] as follows.

**Genkey**: A user’s key $(pk, sk)$ of the DL-type is generated as in Genkey. Additionally, the DL public key $pk = (p, q, g, y, H_1)$ for the trapdoor commitment is also needed. Here, it is required that the secret key is not known by any one. It can be generated as described in the new variant Schnorr digital signature scheme in Section 3.3.

**RSign/RVerify**: A signer $A_k$ generates a controllable ring signature for the message $m$ and the ring $L$, in the following way.

1) Initialization (1) Select $\alpha \in_R Z_q$ and compute $e_k = g^\alpha \mod p$. (2) Compute $e_t = H_1(e_k)$, select $s_t \in_R Z_q$, and then compute $e_t = g^{s_t} y^e \mod p_t$. (3) Compute $e_{k+1} = H_{k+1}(L, m, e_k, e_t).

2) Forward Sequence: For $i = k + 1, \ldots, n - 1, 0, \ldots, k - 1$, select $s_i \leftarrow_R Z_q$ and compute $e_i = g^{s_i} y^{e_t} \mod p_t$ and set $e_{k+1} = H_{k+1}(L, m, e_i, e_t).

3) Forming the ring: Compute $s_k = \alpha - c_k e_k \mod q_k$. The resulting ring signature is

$$\sigma = (c_0, s_0, \ldots, s_{n-1}; pk_t, e_t; pk_0, \ldots, pk_{n-1})$$

and the real signer will store the secret information $(e_t, s_t)$.

A controllable ring signature

$$\sigma = (c_0, s_0, \ldots, s_{n-1}; pk_t, e_t; pk_0, \ldots, pk_{n-1})$$

for the message $m$ is verified as follows. For $i = 0, \ldots, n - 1$, compute $e_i = g^{r_i} y^{e_t} \mod p_t$ and then compute $c_{i+1} = H_{i+1}(L, m, e_i, e_t)$ if $i \neq n - 1$. Accept if $c_0 = H_0(L, m, c_{n-1}, e_t)$. Reject otherwise.

Note that we refer the reader to the 3 facts in the next section for the basic idea underlying the above construction and the next protocols or algorithms.

**Alldentify**: For a valid controllable ring signature $\sigma = (c_0, s_0, \ldots, s_{n-1}; pk_t, e_t; pk_0, \ldots, pk_{n-1})$ of the message $m$, the real signer anonymously proves his authorship of $\sigma$ through a zero-knowledge proof of knowledge of $(e_t, s_t)$ s.t. $e_t = g^{s_t} y^{e_t} \mod p_t$ as follows:

1) The verifier randomly chooses $e', s', t', t'_2$ and computes $e' = g^{s_t} y^{e_t} \mod p_t$, $x' = g^{t'_1} y^{e_t} \mod p_t$. Then $(e', x')$ is sent to the prover.

2) The real signer picks random numbers $t_1, t_2 \in Z_{q_t}^*$ and computes $x = g^{t_1} y^{e_t} \mod p_t$. Then the real signer randomly selects $r'_1, r'_2, z' \in Z_{q_t}$ and computes $x'' = g^{r'_1} y^{r'_2} e^{z''} \mod p_t$. Next the real signer randomly selects $z' \in Z_{q_t}$. At last, $(x, x'', z')$ is sent to the verifier.

3) The verifier computes $r'_1 = t'_1 - z' e'$ mod $q_t$, $r'_2 = t'_2 - z's'$ mod $q_t$, choose a random number $z \in Z_{q_t}$ and sends $(r'_1, r'_2, z)$ to the real signer.

First, the real signer checks whether $x = g^{r'_1} y^{r'_2} e^{z'} \mod p_t$. If so, the real signer sends to the verifier $z''$, $r'_1$, $r'_2$ and $(z, r_1, r_2)$ such that:

$$z = z'' + z_t, r_1 = t_1 - zc_t, r_2 = t_2 - z s_t.$$  

5) The verifier will accept that the prover is the real signer of $\sigma$ if $x = g^{r'_1} y^{r'_2} e^{z''} \mod p_t$, $x'' = g^{r'_1} y^{r'_2} e^{z''} \mod p_t$ and $z = z'' + z$. Otherwise, he will reject it.

Here note that, as in Def.3, we implicitly assume that the verifier has obtained the authentic ring signature before he requires the anonymous proof. In fact, this can be easily implemented. For example, he can sign the ring signature using his secret key, sends it to the real signer and requires anonymous proof for the authorship of this signed ring signature.

**SSign/SVerify**: For a valid ring signature $\sigma = (c_0, s_0, \ldots, s_{n-1}; pk_t, e_t; pk_0, \ldots, pk_{n-1})$ on the message $m$, the linkable signature $(z, r_1, r_2)$ on a message $m'$ is generated as follows:

$$t_1, t_2 \leftarrow_R Z_{q_t}, x = g^{t_1} y^{t_2} \mod p_t, z = H_1(m', x),$$

$$r_1 = t_1 - z c_t \mod q_t, r_2 = t_2 - s t \mod q_t.$$  

The verifier will accept that $(z, r_1, r_2)$ and $\sigma$ is signed by the same anonymous signer if $H_t(m', g^{t_1} y^{t_2} e^{r_2} \mod p_t) = z$ and reject otherwise.

**Conver/CVerify**: To convert a controllable ring signature $\sigma$, the real signer $A_k$ releases the relative $s_t$ such that $e_t = ...
interactive proof of knowledge of controllability, the real signer should present a non-

is a valid controllable ring signature due to the party \(A_k\).

To check whether \((\sigma, r)\) is a valid converted ring signature due to the party \(A_k\), the verifier checks whether \(\sigma\) is a valid controllable ring signature through \(RVerify\) and checks whether

\[
e_t = g_t^{\sigma t} \mod p_t.
\]

where \(c_0\) is computed as in \(RVerify\).

Remark 1: In the above scheme, given a controllable ring signature, there is no way for the receiver to check whether this ring signature can be correctly converted. In other words, for a controllable ring signature, the verifier can only check whether it is generated by a ring member but can not check whether it is controllable. However, in some applications, it may be necessary for the verifier to be convinced of the convertibility. In fact, the above scheme can be easily extended to support a non-interactive proof for the convertibility of the controllable ring signature. We will show that the proof for controllability can be implemented using 1-out-of-\(n\) witness indistinguishable proofs with a concrete discrete logarithm setting [21].

Concretely speaking, to convince the receiver of the controllability, the real signer should present a non-interactive proof of knowledge of \((e_t, s_t)\) such that:

\[
e_t = g_t^{e_t} \mod p_t,
\]

\[
e_t \in \{H_t(e_0), H_t(e_1), \ldots, H_t(e_{n-1})\}
\]

where \(e_t = g_t^{s_t} \mod p_t\) for \(i = 0, \ldots, n - 1\). The above proof is equivalent to the proof knowledge of \(s_t\) such that

\[
e_t g_t^{-e_t} = y_t t \mod p_t,
\]

\[
e_t \in \{H_t(e_0), H_t(e_1), \ldots, H_t(e_{n-1})\}.
\]

In other words, the real signer should prove knowledge of one of the \(n\) logarithms \(\log_y(e_t g_t^{H_t(e_0)})\), \(\log_y(e_t g_t^{H_t(e_1)})\), \ldots, \(\log_y(e_t g_t^{H_t(e_{n-1})})\). According to [21], this kind of non-interactive proof of 1-out-of-\(n\) knowledge in a concrete discrete logarithm setting can be easily constructed.

V. SECURITY ANALYSIS

Before analyzing the security of the above controllable ring signature, we first point the following simple facts about the basic tools in our scheme without detailed explanation:

Fact 1. RSing/RVerity is same to the ring signature (all discrete case) proposed in [6] except that \(e_t\) is inserted in our controllable ring signature.

Fact 2. Adentify is a zero-knowledge proof of knowledge of \((e_t, s_t)\) satisfying \(e_t = g_t^{e_t} y_t s t \mod p_t\).

Sketch of proof: This protocol is modularly constructed by applying the paradigm proposed in [17] to the honest-verifier zero-knowledge proof of knowledge of the opening of the Pedersen’s commitment [15]. In more details, the verifier first present the commitment \(e_t\) of the value \(t_1\) and then proves the knowledge of the opening. Next, the proof proves that he knows the opening of \(e_t\) or \(e_t\). The fact that Adentify is zero-knowledge proof of knowledge of \((e_t, s_t)\) can be modularly derived from the paradigm [17]. Here we omit the proof from scratch.

Fact 3. SSign/SVerify is transformed from the identification protocol based DLP (Here the public key is \(e_t = g_t^{e_t} y_t s t\) and \((e_t, s_t)\) is the secret key) due to Okamoto [15] via the Fiat-Shamir technique [16].

Based on the above facts, we can easily analyze the security of our proposed controllable ring signature informally.

Theorem 1: The above scheme is unconditionally anonymous.

Proof (1). From the probabilistic process of RSign, we can see that: (a) all \(s_t, 0 \leq i \leq n - 1\), are randomly distributed in \(Z_q\); (b) \(e_t\) is randomly distributed in \(Z_q\), and \(e_t\) is randomly distributed in \(Z_q\); (c) \(c_0\) is also fixed when \(L = \{pk_i\}^n, m, e_t, c_k, s_0, \ldots, s_{n-1}\) are fixed. So for fixed \(L, m, \) the distribution of \((e_t, c_0, s_1, \ldots, s_{n-1})\) is independent of the public key of the real signer.

(2). First, the protocol Adentify is zero-knowledge secure against cheating verifiers. Especially, it is witness-indistinguishable since the proof is independent of which of \(\{(e_t, s_t)|e_t = g_t^{e_t} y_t^{s t} \mod p_t\}\) is used by the prover. Second, the linkable signature \((z, r), (z, r)\) is determined by the random chosen \((t_1, t_2)\) and independent of which of \(\{(e_t, s_t)|e_t = g_t^{e_t} y_t^{s t} \mod p_t\}\) is used by the signer. So there is no information of \((e_t, s_t)\) leaked through the protocol Adentify and the linkable signatures.

Combining (1) and (2), we can see that for a controllable ring signature, the ring signature itself, the anonymous proof of authorship and the linkable signatures are all independent of which of \((e_t, s_t)\) in \(\{(e_t, s_t)|e_t = g_t^{e_t} y_t^{s t} \mod p_t\}\). So we can conclude that the identity of the real signer is unconditionally protected as long as the real signer does not exposes his identity to the verifier.

Theorem 2: The above scheme is uncontrollable.

Proof Let \(\sigma = (e_0, s_0, \ldots, s_{n-1}; pk_t, c_t; pk_0, \ldots, pk_{n-1})\) be a controllable ring signature where \(e_t = g_t^{e_t} y_t s_t \mod p_t\).

From the Fact 2.3, it is obvious that the attacker can control a controllable ring signature through any of Aldentify, SSign, Convert only if he know \((e_t, s_t)\) s.t. \(\sigma_t = g_t^{e_t} y_t^{s t} \mod p_t\). However, before the real signer publishes \((s_t, e_t)\), \(e_t\) is unconditionally hidden in \(e_t\). And the attacker cannot get \((c_t, s_t)\) by accessing the oracle corresponding to Aldentify since Aldentify is zero-knowledge. Neither can the attacker get \((c_t, s_t)\) by querying the \(O_S\) oracle because of Fact 3. So before \((e_t, s_t)\) is public, no non-singer can control the controllable ring signature.

According to CVerify, if \((\sigma, s_t)\) and \((\sigma, c_t)\) are valid converted ring signatures due to \(A_r\) and \(A_r\) respectively, then we have \(e_t = g_t^{e_t} y_t^{c_t} = g_t^{e_t} y_t^{s t} \mod p_t\), where
queries its challenger on the message \( m \), the ring \( L \subseteq \mathcal{L} \). Let \( \sigma \) be \((c_0, s_0, \ldots, s_{n-1}; p_k; e_i; p_i; 0, \ldots, p_{k-1})\). If \( p_k = p_k^* \), then \( \mathcal{F}_2 \) returns \((c_k, s_k, r)\) as the signature on the message \( m' = (L, m, e_{k-1}) \). If \( p_k \neq p_k^* \), \( \mathcal{F}_2 \) aborts. Here, it is obvious that \( c_k = H(L, m, e_{k-1}, g_t^i (g_k^e y_{t-k}^e) \mod p_k) \mod y_t^e \) if \((\sigma, r)\) is valid converted ring signature due to \( p_k^* \).

Now, we analyze the probability that \( \mathcal{F}_2 \) does not aborts. Note that in the above simulation, all the public keys in the \( L \) play the same roles and \( p_k^* \) cannot be distinguished from the other public keys. Since at least one public key in the \( L \) is not corrupted, so the probability that the public key \( p_k^* \) is not queried on the oracle \( O_K \) is at least \( \frac{1}{|L|} \). The probability that \( \mathcal{F}_1 \) returns the converted ring signature corresponding to \( p_k^* \) is at least \( \frac{1}{|L|} \). So the probability that \( \mathcal{F}_2 \) does not aborts is at least \( \frac{1}{|L|} \). Since a valid converted ring signature \((\sigma, r)\) implies that \( c_k = H(L, m, e_{k-1}, g_t^i (g_k^e y_{t-k}^e) \mod p_k) \mod y_t^e \), \( c_k, s_k, r \) is just a digital signature with respect to the signature scheme in Section 3.3 with the public key \( p_k^* \) and the message \( m' = (L, m, e_{k-1}) \). So if \( \mathcal{F}_1 \) can succeed in forging a valid converted ring signature with probability larger than \( \epsilon_1 \), then \( \mathcal{F}_2 \) succeeds in attacking the digital signature scheme in Section 3.3 with probability \( \epsilon_2 \geq \frac{1}{|L|} \epsilon_1 \). By Lemma 1, the II-unforgeability of our controllable ring signature is obtained.

VI. E-PROSECUTION SCHEME BASED ON CONTROLLABLE SIGNATURES

In this section, based on the above controllable signature scheme, we design the E-prosecution scheme as follows. This E-prosecution scheme involves two parties: the public authority such as the police office, and the group (ring) of all possible prosecutors. By this scheme, the prosecutor can prosecute sequential messages First and \( i \)-th offline prosecution, and even anonymously initiates an online discussion with the authority (Online Anonymous Prosecution), and collect the reward by opening this identity to authority (Award Collection). As will be shown in the security analysis, this E-prosecution can well protect the identity privacy of the prosecutor.

- **System Setup:** In this phase, the public authority \( A_i \) and the possible prosecutors \( A_i \) (0 ≤ \( i \) ≤ \( n-1 \)) generates their public/privat key pairs respectively. Just like Genkey, for each possible prosecutor \( A_i \) indexed by \( i \), let \( p_i, q_i \) be large primes. Let \( \langle g_i \rangle \) denote a prime subgroup of \( \mathbb{Z}_p \) generated by \( g_i \), whose order is \( q_i \). Choose a random \( x_i \in \mathbb{Z}_{q_i}^* \) as the secret key and set \( y_i = g_i^{x_i} \mod p_i \). Let \( H_i : \{0,1\}^* \rightarrow \mathbb{Z}_{q_i} \) be publicly available hash functions. Let \( p_k^* = (p_i, q_i, g_i, y_i, H_i) \) be the DL public key of the ring member \( A_i \). Let \( L \) be the set \( \{p_k^*\}_{k=0}^{n-1} \). Similarly, the public authority \( A_i \),
generates his public key \( pk_i = (q_i, g_t, y_t, H_t) \) and the private key \( x_i \) such that \( y_t = g_t^{x_i} \).

- **First Offline Anonymous Prosecution:** In this phase, the real prosecutor \( A_0 \) decides the first prosecution message \( m_1 \), generates the ring signature \( \sigma_1 = (c_0, s_0, \ldots, s_{n-1}, pk_1, e_1, pk_1, \ldots, pk_{n-1}) \), by running the algorithm RSIngn. Then the real prosecutor sends \((\sigma_1, m_1)\) to the authority. The authority can check whether this prosecution comes from one of the ring by running the algorithm RSIngn.

- **i-th Offline Anonymous Prosecution \((i > 1)\):** Here, our prosecution scheme can provide the real prosecutor the ability to continue prosecuting some messages. In this way, the receiver can check whether these sequential prosecuted messages come from the original prosecutor, although the real prosecutor remains anonymous. In this phase, to prosecute the \(i\)-th message \(m_i\), the real prosecutor \( A_k \) generates the signature \( \sigma_i = (z_i, r_i, t_i) \) by running the algorithm SSIngn. Then he sends \((\sigma_i, m_i)\) to the authority. By running \(RVIngn, SVIngn\), the authority can check whether these two signature were generated by the same prosecutor which is anonymous in the ring.

- **Online Anonymous Prosecution.** In some cases, the online anonymous discussion between the real prosecutor \( A_k \) and the authority \( A_t \) may be needed. For example, required by the prosecutor or the authority, the real prosecutor may call the the authority for discussing some details on his prosecution. To this end, the prosecutor can anonymously authenticate himself by running the protocol AIdentify. Once the anonymous authentication is accepted, the authority can assure the real prosecutor anonymously and can discuss some details on the prosecution with the prosecutor.

- **Award Collection.** At last, after running Convert, the real prosecutor \( A_k \) can prove that he is the real prosecutor by showing \( s_t \) such that \( e_t = g_t^{H_t(g_y^k \mod p)} \mod p \). By running CVerIfity, the authority can check this fact. If the authority accepts, the real prosecutor will get his reward.

Next, we analyze the security of the above E-Prosecution scheme.

- The prosecutor remains anonymous even after he opens this identity to the authority. Before opening the commitment \( e_t = g_t^{x_t} y_t^{s_t} \), the identity relative information \( e_t = H_t(e_k) \) is uncontrollably secret in the information theory sense. This is because for every possible value of \( e_t = H_t(e_k) \) \((k' \neq k) \) corresponding to any possible prosecutor in the ring, there exists a value \( s_t \) such that \( e_t = g_t^{x_t} y_t^{s_t} \). After opening \((e_t, s_t)\) to authority, the authority can generate one value \( s_t \) for any value \( e_t = H_t(e_k) \) \((k' \neq k) \). Since he can arbitrarily open \( e_t \) for any possible prosecutor in the ring, any third party will not believe the authority’s opening. Hence, the prosecutor always remains secure.

- After the first offline prosecution and before award collection, only the real prosecutor knows the opening \((e_t, s_t)\) for the commitment \( e_t = g_t^{x_t} y_t^{s_t} \), according to the discrete logarithm assumption. Here note that before the real prosecutor discloses his identity to the authority, even the authority himself can not open the commitment. In fact, directly opening \( e_t \) still means solving the discrete logarithm for the authority. Of course, after the prosecutor open the commitment to the authority, he can arbitrarily open the commitment using his secret key as the trapdoor. Hence, only the real prosecutor can make sequential offline prosecution, anonymous online prosecution and award collection.

- If the prosecutor wants to further make the prosecuted message secret, he can (1) generate all the relative signatures on the commitment \( m' = g_t^{\delta_t} y_t^{\eta_t} \) instead of the message \( m \), (2) encrypt the message \( m \) into the ciphertext \( c \) using a certain public key encryption scheme with the \( y_t \) as the public key, (3) and sends the relative signature \( \sigma \), the partial opening value \( r \) and the ciphertext \( c \) to the prosecutor. In this way, firstly, any third party can not obtain the message \( m \) from the communication procession. Secondly, the authority can not prove to one third party that there is one prosecutor who prosecuted the message \( m \). This because the authority can use his private key as the commitment trapdoor to arbitrarily open the commitment \( m' = g_t^{\delta_t} y_t^{\eta_t} \) for any possible message \( m \).

- The real prosecutor cannot frame any other party in the ring. The reason is that after the prosecution, if the real prosecutor wants to maliciously claim that it is not himself but a certain other party \( A_{k'} \) who made the prosecution, he will face the problem of working out a new opening \( s'_t \) for \( e_t = g_t^{x_t} y_t^{s'_t} \) where \( e'_t = H_t(g_k^{s_k} y_k^{s'_k} \mod p) \). Without the trapdoor \( x_t \) such that \( y_t = g_t^{x_t} \), this operation is infeasible for the real prosecutor.

**VII. CONCLUSION**

In this paper, we revisited the classic application of a ring signature in leaking secrets and point out a list of problems unsolved by a standard ring signature. Motivated these problems, we formalized a new cryptographic concept called a controllable ring signature and propose a concrete scheme. This extension of a standard ring signature can fully ensure the interests of the real signer: (1) the real signer remains unconditional anonymous as long as he does not remove anonymity; (2) only the real signer can control the ring signature: only he can anonymously prove the authorship, generate a linkable ring signature or convert it. On the other hand, a ring member is rightly restricted since he can not generate a controllable ring signature and convince one that it is generated by others. At last, using this controllable
ring signature scheme, we design a secure E-prosecution scheme.

Acknowledgement. We would like to express our gratitude thanks to the anonymous referees of WISA 2006 for their invaluable suggestions to improve this paper.
