Comparison of thermal stability in MAX211 and 312 phases

Abstract
The susceptibility of four MAX phases (Ti2AlC, Cr2AlC, Ti3AlC2, and Ti3SiC2) to high-temperature thermal dissociation in vacuum has been investigated using in-situ neutron diffraction.

Abstract. The susceptibility of four MAX phases (Ti\(_2\)AlC, Cr\(_2\)AlC, Ti\(_3\)AlC\(_2\), and Ti\(_3\)SiC\(_2\)) to high-temperature thermal dissociation in vacuum has been investigated using in-situ neutron diffraction. In high vacuum, these phases decomposed above 1400°C through the sublimation of M and A elements, forming a surface coating of MC. The apparent activation energies for the decomposition of sintered Ti\(_3\)AlC\(_2\), Ti\(_3\)SiC\(_2\), and Ti\(_2\)AlC were determined to be 179.3, -71.9, and 85.7 kJ mol\(^{-1}\), respectively. The spontaneous release of Ti\(_2\)AlC and TiC from de-intercalation during decomposition of Ti\(_3\)AlC\(_2\) resulted in a negative activation energy.

1. Introduction
A group of layered ternary ceramics with the general formula \(M_{n+1}AX_n\) \((n = 1-3, M\) is an early transition metal, \(A\) is a group \(A\) element, and \(X\) is either carbon and/or nitrogen) were found to be excellent candidate materials for high temperature applications, due to the unique combination of both metallic and ceramic properties [1-6]. MAX phases are layered hexagonal (space group \(P_6_3/mmc\)) \(Z = 2\). In brief, the \(M_X\) octahedra are edge sharing and are identical to the \(NaCl\)-type structure of the corresponding binary carbides. These \(M_X\) octahedra are interleaved by close-packed planes of the \(A\) element [7-10]. Ternary carbides such as Ti\(_3\)AlC\(_2\), Ti\(_3\)SiC\(_2\), Ti\(_2\)AlC, and Cr\(_2\)AlC are common representatives of the MAX phases. The electrical and mechanical properties, and the oxidation of these four compounds has been well studied [9, 11-21], however, very little is published on their susceptibility to high-temperature phase dissociation in vacuum.

In this paper, the thermal stability and the corresponding phase dissociation of these ternary carbides in vacuum was investigated using high-temperature in-situ neutron diffraction. The apparent activation energies of phase decomposition were calculated. The characteristics of thermal stability in MAX 211 (Ti\(_2\)AlC and Cr\(_2\)AlC) and 312 phases (Ti\(_3\)AlC\(_2\) and Ti\(_3\)SiC\(_2\)) are compared and discussed.

2. Experimental
The collection of high-temperature in-situ neutron diffraction data were collected using Wombat (the high-intensity neutron powder diffractometer) at the OPAL source in Australia. Data were collected using neutrons with incident wavelength of \(\lambda = 1.660\) Å from 15 to 135° 2\(\theta\) with a step size of 0.125°, with the use of the oscillating tertiary collimator. Rietica 1.7.7 was used for phase
identification and Rietveld refinement. The optimized parameters during refinement were background coefficients, zero-shift error, peak shape parameters, cell parameters, and anisotropic thermal factors. The residual values of the refinement, statistical reliability factor of Bragg ($R_B$), R-weighted pattern ($R_w$), R-expected ($R_{\text{exp}}$), and the goodness-of-fit ($\chi^2$), were evaluated. In Rietica, $\chi^2$ is defined as the square of the ratio of $R_w$ to $R_{\text{exp}}$.

Fully-dense solid bars of hot-isostatically-pressed Ti$_2$AlC, Cr$_2$AlC, Ti$_3$SiC$_2$, and spark-plasma sintered Ti$_3$AlC$_2$ were used in this study [2, 16]. The temperature of sample environment was controlled by a closed cylindrical niobium vacuum furnace $(10^{-6}-10^{-8}$ torr). The sample was held by vanadium wire and heated to 1000°C at a heating rate of 10°C/min and thereafter at 5°C/min to 1550°C. The dwell times at between 1000 and 1550°C are shown in Table 1. Diffraction patterns were collected every minute from starting to the end of the experiment.

The decomposition rates at different temperatures were calculated and the corresponding apparent activation energies were determined in order to understand further the mechanism of high-temperature phase dissociation in vacuum.

### 3. Results and Discussion

#### 3.1 Phase Transitions during Thermal Dissociation of MAX 211 and 312 Phases

The phase evolution of MAX phases and the relative phase abundances at various temperatures as revealed by in-situ neutron diffraction is shown in Figure 2. The samples used in this experiment were not single-phase with TiC as the most common impurity. The starting compositions of each sample are shown in Figure 2. For Ti$_3$SiC$_2$, it decomposed to TiC above 1300°C (Fig. 2a). A weight loss of ~ 4% was observed for decomposed Ti$_3$SiC$_2$ which may be attributed to the release of gaseous Ti and Si by sublimation during the decomposition process. These results agree with those reported by Low and co-workers [22-23]. For Ti$_3$AlC$_2$, its decomposition into TiC and Ti$_2$AlC as lower order or intermediate phase was observed at ≥ 1400°C (Fig. 2b). However, at higher temperatures, when compared to TiC, a smaller growth rate for Ti$_2$AlC may indicate that Ti$_2$AlC experienced further decomposition into TiC via the sublimation of Al and Ti, similar to decomposition of Ti$_3$SiC$_2$. In contrast to Ti$_3$AlC, no intermediate or lower order phase was observed for the decomposition of Ti$_3$SiC$_2$. This difference can be attributed to the fact that Ti$_3$SiC$_2$ is the only stable ternary phase in Ti-Si-C system. For Ti$_3$AlC (Fig. 2c), the formation of TiC results mainly from the decomposition of Ti$_3$AlC$_2$ as the impurity phase. Ti$_2$AlC would only decompose above 1450°C by sublimation of Ti and Al. Figure 2(d) shows the excellent stability of Cr$_2$AlC up to 1450°C where no observable phase dissociation was detected. However, it started to react with the vanadium wire and became unstable above 1450 °C. Like Ti$_3$AlC, it would only decompose above 1450°C via the sublimation of Cr and Al.

The existence of a lower order 211(Ti$_2$AlC) phase in Ti$_3$AlC$_2$ is believed to be responsible for its unique two-step decomposition behaviour when compared to Ti$_3$AlC, Cr$_2$AlC, Ti$_3$SiC$_2$ which do not possess such a lower order phase. As a consequence, the former undergoes an initial spontaneous decomposition to lower order Ti$_2$AlC phase, followed by eventual decomposition of Ti$_2$AlC through the sublimation of Al and Ti at higher temperature. On the contrary, the latter decompose at elevated temperature in vacuum through the direct sublimation of M and A elements with the concomitant release of a binary carbide (MX) as follows:

$$M_{n+1}AX_n \rightarrow nMX + A + M$$
3.2 Apparent Activation Energies During Isothermal Decomposition

During the isothermal decomposition of 211 and 312 phases at different temperatures, the decomposition rates were calculated by analyzing the relationship between the phase abundances and soaking time. These rates were used to determine the corresponding apparent activation energy of decomposition using an Arrhenius equation [24],

\[ k = A \exp\left(\frac{-E}{RT}\right) \]

where \( k \) is the reaction rate, \( E \) is activation energy, \( R \) is gas constant, \( T \) is absolute temperature and \( A \) is a constant.

The calculated apparent activation energies for the four MAX phases and the proposed reactions are summarized and listed in Table 1.

Table 1. Comparison of the decomposition of MAX 211 and 312 phases.

</tbody>
</table>

A negative activation energy obtained for Ti$_3$AlC$_2$ can be attributed to the presence of weak Ti-Al bonds [25] which will favour spontaneous decomposition through the de-intercalation of TiC from the crystal structure (see Eq 2a). Subsequent decomposition of released Ti$_2$AlC at higher temperature (see
Equation 2b) would involve a small but positive activation energy. It follows that the high activation energy obtained for Ti$_3$SiC$_2$ can be attributed to much stronger bonding between Ti and Si, leading to better resistance against thermal dissociation via sublimation of Ti and Si from the crystal structure. The lower but positive activation energy observed for decomposition of Ti$_2$AlC (see Eq. 3) is related to weaker Ti-Al bonds and thus its susceptibility to sublimation in vacuum at elevated temperature.

4. Conclusions
The high-temperature thermal stability of MAX 211 and 312 phases in vacuum has been studied using in-situ neutron diffraction. Both 211 and 312 phases were susceptible to decomposition above 1400°C through sublimation of M and A elements, resulting in a surface coating of TiC being formed. The apparent activation energies for the decomposition of sintered Ti$_3$SiC$_2$, Ti$_3$AlC$_2$ and Ti$_2$AlC were determined to be 179.3, -71.9 and 85.7 kJ mol$^{-1}$, respectively. The negative activated energy for Ti$_2$AlC$_2$ can be attributed to the release of lower order Ti$_2$AlC and TiC from the crystal structure via spontaneous de-intercalation.
