Background and Aims: Leucine-rich repeat and immunoglobulin domain-containing protein Lingo-1, is a potent negative regulator of both axonal myelination and neurite extension. The Nogo receptor (NgR)/TNF receptor orphan Y (TROY) and/or p75 complex, With No Lysine (K) (WNK1) and Myelin transcription factor-1 (Myt1), have been reported as co-receptors or co-factors in Lingo-1 signaling in the brain. We aimed to investigate the developmental profile of Lingo-1 signaling proteins in a phencyclidine (PCP) neurodevelopmental rat model of schizophrenia.

Methods: Male Sprague Dawley rats received s.c. injections of PCP (10mg/kg) or saline at postnatal days (PN)7, 9 and 11. Rats (n=6) were sacrificed at three time points, PN12, 5 weeks or 14 weeks. We examined the relative protein expression levels of Lingo-1, NgR, p75, TROY, WNK1 and Myt1, as well as Myelin Basic Protein (MBP) and Myelin Oligodendrocyte Glycoprotein (MOG) as markers of myelination within the prefrontal cortex of the treated rats.

Results: At PN12, Myt1 was decreased in the PCP treated rats, (10; p=0.044). There were no significant changes in the expression of any of the tested proteins at PN 5 weeks (0.129≤p≤0.909). At PN 14 weeks, Lingo-1, NgR, TROY and WNK1 were increased in the PCP treated rats (7%-18.5%; 0.002≤p≤0.036). No alterations in myelination markers were found in any group (0.208≤p≤0.986).

Conclusions: This is the first study to have shown an alteration of Lingo-1 signaling pathways in the PFC in a neurodevelopmental schizophrenia animal model. This will allow us to gain a better understanding of the mechanisms implicated in schizophrenia.
