CONCENTRATION AND DISTRIBUTION OF SIALIC ACID IN SOW MILK DURING LACTATION
M. Jahan, P. Wynn, B. Wang, EH Graham Centre for Agricultural Innovation, Charles Sturt University, NSW, Australia
E-mail address: mjahan@csu.edu.au (M. Jahan)

Background/Aims: Human milk sialic acids has been proposed as a bioactive compound promoting immune function, gut maturation and neurodevelopment of the newborn. Porcine milk however, has received little attention. The aims of the present study were to quantify and compare the levels of N-acetylmuramic acid (Neu5Ac), N-glycolylmuramic acid (Neu5Gc) and ketodeoxynuclidonic acid (KDN) in sow milk during course of lactation.

Method: Milk samples from 22 sows were collected by manual expression on 3 occasions, day 1 (colostrum), day 3 (transition milk) and day 15-21 (mature milk) respectively. The concentration of Neu5Ac, Neu5Gc and KDN were analyzed using UHPLC.

Results: Sow milk contained significant amounts of Sia with the highest concentration found in colostrum (1238.50 mg/L) followed by transition milk and then mature milk. Neu5Ac was the major form of Sia (93.96%) and then Neu5Gc (3-6%), KDN however contained as little as 1-2%. This distribution was common to each milk fraction and to each time point in lactation.

Conclusions: Porcine milk contained a rich source of sialylated glyco-conjugate, the predominately form of sialic acid is Neu5Ac. The high concentrations of Sia in porcine milk suggest that Sia is an important nutrient that may contribute to the optimization of immune function, neuro-development and growth and development of piglets.

MOLECULAR MECHANISMS DRIVING AIRWAY INFLAMMATION FOLLOWING A HIGH-FAT MIXED MEAL IN ASTHMA
Q. Li 1, K.J. Baines 1, P.G. Gibson 1,2, L.G. Wood 1. 1 Centre for Asthma and Respiratory Diseases, Hunter Medical Research Institute, University of Newcastle, NSW, Australia; 2 Department of Respiratory and Sleep Medicine, John Hunter Hospital, NSW, Australia
E-mail address: c3156151@unnewcastle.edu.au (Q. Li)

Background/Aims: A high fat meal is associated with airway inflammation in asthma, but the mechanisms are not well understood. This aim of this study was to use microarray techniques to examine the molecular mechanisms of fat-induced airway inflammation in asthma compared with healthy controls.

Methods: Subjects with asthma (n = 11) and healthy controls (n = 8) were provided with a high-fat, high energy meal, containing total energy (TE) of 3846 kJ and 48 g (49% of TE) total fat, including 20.5 g (21% of TE) saturated fat. Sputum was induced at 0 and 4 hours and gene expression was examined by microarray and quantitative real-time PCR (qPCR).

Results: Following the high fat dietary challenge, 168 entities were significantly differentially expressed greater than 1.5 fold in subjects with asthma. Five genes involved in immune system processes were selected for qPCR analysis (S100P, S100A16, MAL, MUC1 and NLRP12). qPCR confirmed that S100P, S100A16, MAL and MUC1 were significantly increased in the asthma group post-meal. There was a moderate and significant correlation between the change in S100P and MUC1 gene expression and the change in sputum %neutrophils following the high fat meal (r = 0.552, p = 0.024; r = 0.495, p = 0.045 respectively). NLRP12 gene expression at 4 hours strongly correlated with the change in total and saturated non-esterified plasma fatty acid levels at 2 hours (r = 0.555, p = 0.028; r = 0.53, p = 0.037 respectively).

Conclusions: Our data identifies several genes that contribute to neutrophilic airway inflammation following consumption of a high fat meal in asthmatics, which may prove to be therapeutic targets for immunomodulation.

DOES INCREASED INTAKE OF FOLIC ACID INCREASE CANCER RISK?
D. Mackerras, J. Tan, C. Larner. Food Standards Australia New Zealand, ACT, Australia
E-mail address: dorothy.mackerras@foodstandards.gov.au (D. Mackerras)

Background/Aims: Food Standards Australia New Zealand monitored the literature regarding cancer risk following mandatory fortification with folic acid to reduce the risk of neural tube defects in Australia.

Methods: Randomised controlled trials testing folic acid for at least one year and reporting any of: all-cause mortality, total cancer, four selected cancers or recurrence of colorectal adenoma in healthy non-pregnant adults were identified by searching in PubMed and CENTRAL from 2001 onwards. Random effects meta-analysis of the relative risks was conducted using StatsDirect (http://www.statsdirect.co.uk).

Results: Twenty-six trials, lasting up to 7.3 years, were identified from 4216 abstracts. The larger trials generally described masked allocation and blind outcome assessment. The 13 trials (43,557 subjects) reporting total cancer incidence yielded a non-significant overall relative risk (RR) of 1.04 (95%CI: 0.97-1.11). Fewer studies reported results for colorectal cancer RR = 1.00 (95%CI: 0.82-1.23), breast cancer RR = 0.82 (95%CI: 0.63-1.07), lung cancer RR = 1.00 (95%CI: 0.84-1.21) or prostate cancer RR = 1.16 (95%CI: 0.85-1.60). Only the results for prostate cancer indicated any heterogeneity (I² = 52.7%). Most data comes from large trials testing 0.8-2.5 mg/day.

Conclusions: There are no significant increases or decreases in cancer risk. Other meta-analyses using different inclusion criteria to select studies have found similar results. The amount of folic acid used in mandatory fortification in Australia is about one-tenth of that tested and the effect on blood folate levels has been commensurately lower.

SAFETY OF EMU OIL FOR INTESTINAL APPLICATIONS
S. Mashtoub 1,2, K.Y. Cheah 3, K.A. Lynn 1,4, G.S. Howarth 1, L. Detectable Oil Therapy Department, Women’s & Children’s Hospital, North Adelaide, SA, Australia; 2 School of Medicine & Pharmacology, Uni. of Western Australia, WA, Australia; 3 School of Animal & Veterinary Sciences, Uni. of Adelaide, SA, Australia; 4 Women’s & Children’s Health Research Institute, North Adelaide, SA, Australia
E-mail address: susanne.mashtoub@uwa.edu.au (S. Mashtoub)

Background/Aims: Previously, we have reported that Emu Oil (EO) lengthens intestinal crypts, a feature of intestinal growth, in experimental colitis (2012) and mucositis (2013). However, it remains unclear whether the recovery of normal intestinal growth following withdrawal of EO therapy supports its safety for intestinal conditions.

Methods: Dark Agouti rats (n = 8/group) were gavaged daily for 10 days with Water, Olive Oil (OO) or EO (0.5 mL) or 0.5 mL EO (0.5EO). Rats were euthanized on day 10 or day 17. Intestinal weights, lengths, villus height and crypt depth measurements in EO-treated rats returned to normal levels following withdrawal of EO therapy.

Results: On day 10, jejuno-ileum (JI) weight was increased by OO (26%) and EO (0.5 mL: 15%; 1 mL: 29%; p < 0.01), which was normalised by day 17. On days 10 and 17, JI length was greater in OO- (12%) and EO-treated rats (0.5 mL: 8%; 1 mL: 12%; p < 0.05) relative to water controls. On day 10, OO and EO increased jejunal VO (OO: 32%; 0.5EO: 22%; EO: 35%; p < 0.01) and CD (OO: 17%; 0.5EO: 13%; EO: 22%); importantly however, after withdrawal of all oils, VO and CD returned to normal levels. Moreover, the VH:CD ratio (a feature of dysplasia) was unaffected in all oil-treated rats compared to normal controls.

Conclusions: The restoration of normal intestinal growth following cessation of Emu Oil therapy supports its safety for intestinal conditions.

DIETARY FISH OIL AT LOW INTAKES INCREASES DHA INCORPORATION AND REDUCES LOW FREQUENCY FATIGUE IN RAT HINDLIMB SKELETAL MUSCLE
Background/Aims: This study aimed to investigate the effect of low dose fish oil diets on skeletal muscle contraction and low frequency fatigue after initial fatiguing stimulation.

Methods: A total of 18 male Wistar rats were fed (for 5w) a 10% fat diet containing: olive oil (OO); or 0.31% (lowFO); or 1.25% moderate (modFO) NuvMega, High-DHA tuna fish oil in OO. The constant-flow autologous blood-perfused hindlimb was prepared in vivo and stimulated via sciatic nerve. Tetanic stimulations preceded low frequency stimulation protocols at 2 Hz continuous and 5 Hz burst.

Results: FO diets increased muscle DHA (gastrocnemius: OO 7.8 ± 0.7; LowFO 20.0 ± 0.1% total phospholipid fatty acids). No difference was found in tetanic force (~200 N/100 g), but rate of tetanic force developed to determine the clarity of values articulated by participants of a Health coaching using behavioural therapy is an intervention aimed to determine the reliability of a criteria-based scoring instrument [Value Articulation Instrument (VAI)], were developed to analyse value clarification of participants. Further modifications of daily activities of living warrants further investigation in human studies.

Background/Aims: Depression and anxiety are common in women with polycystic ovary syndrome (PCOS). An association between vitamin D deficiency and mood disorders or inflammation has been previously reported in the general population. The aim of this study was to investigate the association between 25 hydroxy-Vitamin D (25OHD) status, anxiety and depression and inflammation in women with (n = 50) and without (n = 23) PCOS.

Methods: Cross-sectional study in overweight or obese premenopausal women with (n = 50) and without (n = 23) PCOS. Primary outcome measures were 25OHD, mood (Hospital Anxiety and Depression questionnaire) and inflammation [high sensitivity C-reactive protein (hsCRP)]. Results were analysed by multiple linear regression.

Results: Vitamin D deficiency (25OHD < 50 nmol/L) (46% vs. 39%, p = 0.311) and 25OHD (50.4 ± 22.2 nmol/L vs. 51.6 ± 19.0 nmol/L = 0.828) were not significantly different in women with and without PCOS. For all women combined, 25OHD was the only significant independent predictor of depression ($β$ ± SE = -0.063 ± 0.021, $p = 0.005$) and hsCRP ($β$ ± SE = -0.041 ± 0.015, $p = 0.010$).

Conclusions: Vitamin D deficiency is common and vitamin D is independently associated with depression and inflammation in overweight women with and without PCOS. Further investigation to clarify the inter-relationship between vitamin D, inflammation and depression is required to identify optimal prevention and treatment strategies for psychological and metabolic dysfunction in PCOS.

NUTRITIONAL PROFILING: ANEMIA, FAT INTAKE AND $\gamma$-TOCOPHEROLS IN A CHINESE COHORT

S. Mutter 1, Z. Shi 2, V.P. Mäkinen 1, 1 Heart Health Theme, School of Medicine, University of Adelaide, SA, Australia; 2 School of Medicine, University of Adelaide, SA, Australia

Background/Aims: The nutritional factors involved in the development of anemia are only partially understood. We conducted a cross-sectional survey to assess their relationships.

Methods: Three-day weighted food records, serum lipids and blood haemoglobin (Hb) were collected for 1306 men and 1537 women (age: 20 – 87 years; mean BMI ± SD: 23.5 ± 3.5 kg/m²) in the Jiangsu longitudinal Nutritional Study in 2002. Participants with anemia (n = 722; 67% women) were matched based on their age, sex, BMI and Hb levels to their closest healthy counterparts.

Results: The median ± SD of the pairwise difference (PD) for the iron intake was lower in individuals living with anemia (PD: -0.4 ± 11.8 mg, NS). Their total cholesterol levels were signifcantly lower (PD: -3.9 ± 52.2 mg/dL). HDL cholesterol and triglycerides levels were lower (PD: -0.8 ± 15.9 mg/dL, NS; -0.4 ± 105.1 mg/dL, NS). Fat intake was significantly increased (PD: 2.4 ± 33.2 g), although vegetable oil and animal fat intake showed no significant difference (PD: -1.2 ± 27.4 g, NS; 0.0 ± 31 g). $\gamma$-tocopherol intake was significantly reduced (PD: -0.6 ± 8.7 mg).

Conclusions: Although patients with anemia ate more fat, the fat-soluble $\gamma$-tocopherol was lower, and they had a more favourable lipid profile. Our preliminary data suggest complex inter-relationships between anemia and nutritional profiles, and we are currently conducting multi-variate analyses on the follow-up study to detect clinically relevant subtypes in the population.
