Nutrition and related claims used on packaged Australian foods - implications for regulation

Abstract

The aim of this study was to describe the use of nutrition and related claims on packaged food for sale in Australia and measure the compliance of such claims with regulations governing their use. A survey was conducted of the labelling of 6662 products in 40 different food categories on sale in New South Wales in 2001. Levels of compliance were assessed by comparing the claims on the label and data in the nutrition information panel with requirements of the Foods Standards Code and the Code of Practice on Nutrient Claims. Half of the products (51.3%) carried some type of nutrition related claim and 36.2% made at least one nutrient claim, with an average of 1.2 nutrition related claims on every food product. The foods with the highest use of nutrient claims were sports drinks, breakfast cereals, meat substitutes, pretzels and rice cakes, muesli bars and yoghurt. The most common nutrient claims were for fat, cholesterol, vitamins, minerals, and sugar. More than 20% of products carried claims related to additives. Many nutrient claims (12.9%) did not comply with current regulations, especially those in the voluntary Code of Practice. Adoption of mandatory requirements for all claims within the Food Standards Code may improve the levels of compliance. Implications for the regulation of nutrition and related claims are discussed. The impact of nutrition claims on consumer purchasing and consumption behaviour deserves further study.

1 **Abstract**

2 The aim of this study was to describe the use of nutrition and related claims on packaged food for
3 sale in Australia and measure the compliance of such claims with regulations governing their use.
4 A survey was conducted of the labelling of 6662 products in 40 different food categories on sale in
5 New South Wales in 2001. Levels of compliance were assessed by comparing the claims on the
6 label and data in the nutrition information panel with requirements of the Foods Standards Code and
7 the Code of Practice on Nutrient Claims. Half of the products (51.3%) carried some type of
8 nutrition related claim and 36.2% made at least one nutrient claim, with an average of 1.2 nutrition
9 related claims on every food product. The foods with the highest use of nutrient claims were sports
10 drinks, breakfast cereals, meat substitutes, pretzels and rice cakes, muesli bars and yoghurt. The
11 most common nutrient claims were for fat, cholesterol, vitamins, minerals, and sugar. More than
12 20% of products carried claims related to additives. Many nutrient claims (12.9%) did not comply
13 with current regulations, especially those in the voluntary Code of Practice. Adoption of mandatory
14 requirements for all claims within the Food Standards Code may improve the levels of compliance.
15 Implications for the regulation of nutrition and related claims are discussed. The impact of nutrition
16 claims on consumer purchasing and consumption behaviour deserves further study.
17

1 **Introduction**

2 In Australia and New Zealand, the most effective regulatory mechanism to manage nutrition and
3 related claims on foods is under discussion. A key element in the management of claims is the
4 extent to which food manufacturers will comply with requirements, either legal or industry-based
5 codes of practice, governing the making of such claims. Examination of current practice regarding
6 nutrition and related claims on foods, and the extent to which food manufacturers are complying
7 with existing laws and industry guidelines, will inform the debate regarding their regulation.

8
9 Nutrition claims on food labels are statements that describe the quantity or quality of the nutritional
10 properties of the food. They may be divided into two categories:

11 *Nutrient claims* relate to particular nutrients that are recognised as essential for normal health. They
12 may be quantitative (eg, high in fibre, low in salt) or qualitative (eg, polyunsaturated).

13 *Other nutrition claims* relate to bioactive substances that may offer particular health benefits (eg,
14 isoflavones), or the general physiological effects of the food (eg, glycemic index).

15 In addition to nutrition claims, there are a number of *nutrition related product description claims*
16 that describe the presence or absence of additives (eg, free of artificial colours), ingredients (eg,
17 lactose free, GM free), make environmental claims (eg, organic, free range) or provide qualitative
18 descriptions of the food (eg, wholegrain, natural).

19
20 Nutrition claims give some interpretive context to numerical data about the nutrient content of
21 foods and provide greater ease of use for consumer decision making; however there is scope for
22 confusion if terminology and formats are not defined [1]. Regulations are needed to ensure that
23 claims on labels are truthful and do not mislead consumers but they should also provide incentives
24 to manufacturers to develop products that promote public health and assist consumers in following
25 dietary recommendations [2]. The position of the Dietitians Association of Australia is that well-
26 defined and monitored nutrient content and comparative claims provide an opportunity to assist
27 consumers to understand the relative nutritional attributes of products [3].

28
29 Nutrition information on labels may help guide consumers to healthier choices [4] and a survey of
30 Australian shoppers in 1991 found that claims about nutrient content were ranked as the second
31 most desirable items of health information on labels after information on additives [5]. Labels can
32 be especially important for food sensitive individuals who may react adversely to specific additives

1 or ingredients [6]. US studies have found label use was significantly associated with lower fat
2 consumption and higher intakes of fruits and vegetables [7, 8]. However, consumers with lower
3 levels of education and health awareness are less likely to use food labels [9]. Evidence also
4 suggests consumers are unable to recognise nutrient claims that are false and that comparative
5 nutrition claims may mislead consumers about the nutritional value of products claims [10, 11].
6 Consumers may have difficulty differentiating between similar claims - for example reduced fat and
7 low fat claims [10] - and may misinterpret some claims: for example a product may be thought low
8 in fat if there is a claim of low cholesterol or low in saturates [12].

9
10 The role of nutrition and related claims in decision-making behaviour is still unclear. Some
11 American studies have suggested that most consumers do not rely primarily on nutrition claims in
12 making overall product and nutrition evaluations when other information such as the nutrition
13 information panel (NIP) is readily available [13, 14]. Research for the US Food and Drug
14 Administration (FDA) has found consumers are highly sceptical of nutrition and health claims on
15 packages because they view them as attempts by manufacturers to sell more of their product [15].
16 Similarly, in Australia and New Zealand in 1991/92 approximately 60-70% of consumers reported
17 being concerned about the honesty of food labels and the enforcement of food regulations [16].
18 Such scepticism can reduce the use of nutrient claims on labels [17] and the acquisition of nutrition
19 information from food labels [18]. On the other hand, in the UK over 80% of people in one study
20 reported that they look at broad nutrition claims (such as low fat, high fibre) and that such nutrition
21 information affects their purchase decisions [19].

22
23 In Australia, a 1995 national consumer survey on food labelling commissioned by the National
24 Food Authority (NFA) reported that 32% of shoppers looked at nutrition claims when purchasing a
25 product for the first time but that about 30% were unsure whether they could trust them [20]. More
26 recent qualitative research commissioned by its successor the Australia New Zealand Food
27 Authority (ANZFA) in both Australia and New Zealand reported that consumers generally liked
28 nutrition claims on packages because they were a quick and easy way to decide between products
29 without reading the entire label, but there was still scepticism about their accuracy, particularly
30 about fat free and 'lite' claims [21].

31

1 Food Standards Australia New Zealand (FSANZ) – formerly ANZFA – now regulates food
2 standards regarding food production, labelling and advertising in Australia and New Zealand.
3 Within the Food Standards Code (FSC) there are general regulations governing the labelling of
4 food, including mandatory information required in the NIP, as well as specific standards for
5 additives (including vitamin and minerals) and some commodity specific labelling regulations (eg,
6 Sports Drinks and Special Purpose Dietary Foods) [22].

7
8 At the time this survey was conducted food standards were in a period of transition. In November
9 2000 Health Ministers in Australia and New Zealand adopted a new version: Food Standards Code
10 Volume 2 (FSC2), which aimed to harmonise regulations between the two countries, reduce the
11 number of product specific standards and completely review horizontal standards applying to all
12 foods, such as those covering labelling [23]. There was a two year transition period starting from
13 the adoption, during which manufacturers were able to comply with either the old Food Standards
14 (FSC1) or the new version [24].

15
16 In addition to the FSC, there is a Code of Practice on Nutrient Claims (COPONC) which was
17 developed in 1995 by the NFA in close consultation with key stakeholders including nutrition
18 experts, the food industry and consumer representatives [25]. The aim of COPONC was to ensure
19 consistent and accurate information about the nutrient content of food on labels to enable
20 consumers to make informed healthier food choices. COPONC was adopted by reference into the
21 Code of Conduct for the Provision of Information on Food Products developed by the food industry
22 [26]. Its administration is the responsibility of the Food Code Management Committee (FCMC),
23 with representatives from industry and the community, and an ANZFA observer, with a secretariat
24 provided by the Australian Food and Grocery Council (AFGC). Since the COPONC is not
25 mandatory, the FCMC cannot impose legal sanctions for breaches, but it attempts to resolve
26 complaints by negotiations with the manufacturers. However, companies do still have obligations to
27 ensure labelling and advertising are neither false nor misleading under the general provision in Fair
28 Trading laws.

29
30 This tripartite system means that the FSC only regulates some claims about the nutrient content of
31 foods. For example, a food cannot be called a source of a vitamin or mineral unless it provides at
32 least 10% recommended dietary intake (RDI) per serve under the standards governing addition of

1 vitamins and minerals to food. Other claims are not regulated in law but are covered by COPONC
2 (for example claims about dietary fibre). For still other nutrient claims (eg, carbohydrate) there are
3 no defined standards, although Fair Trading laws would apply. Table 1 sets out the sections of the
4 FSC or COPONC regulating nutrient and other nutrition related claims. There can be
5 inconsistencies between the provisions of COPONC and general Fair Trading legislation. For
6 example, the criteria for a fat free claim in COPONC allow small trace amounts of fat (up to 0.15%)
7 to be present, whereas a legal interpretation of the term ‘free’ is that fat should be ‘nil’ or ‘not
8 detectable’.

9

10 In May 2001, ANZFA began a review of nutrient content and other related claims, citing a number
11 of problems with the current regulatory arrangements [27]:

- 12 • inconsistency with Codex and international practice
- 13 • non-compliance
- 14 • lack of awareness and/or access by consumers
- 15 • inconsistencies between COPONC and fair trading laws, and
- 16 • inconsistency in relation to imported foods.

17 After a period of public consultation, a draft assessment report was issued in March 2002 with a
18 number of recommendations to change definitions and regulatory arrangements [28]. However, at
19 the same time it was decided that consideration of these recommendations should be combined with
20 the review of Health and Related Claims [29], and a final decision on changes to COPONC was
21 postponed.

22

23 One of the difficulties in reviewing the current nutrition claims regulations has been the lack of
24 comprehensive studies on the extent of the use of such claims on foods sold in Australia. This study
25 aimed to overcome that gap by conducting a survey of a large sample of packaged food products on
26 the Australian market to determine the proportion carrying nutrition and related claims, the wording
27 used to make these claims and their compliance with the COPONC and FSC.

28

1 **Methods**

2 ***Data Collection***

3 In August and September 2001 a survey was conducted of the labels on packaged foods sold in
4 supermarkets in 40 categories of food (Table 2). The survey was conducted by six of the authors
5 (BA, KI, SH, AR, SW, SZ) in Woolworths, Coles, Franklins, Independent Grocers of Australia
6 (IGA) and Aldi supermarkets throughout the Sydney and Wollongong regions. Using a standard
7 record form, the surveyors collected the following information from the product labels:

- 8 • Manufacturer
- 9 • Brand name
- 10 • Flavour variants
- 11 • Number and quantity of available sizes
- 12 • Nutrient claims (ie, those related to the nutrients listed in Table 1)
- 13 • Other nutrition related claims, and
- 14 • Endorsements by health related and other organisations.

15
16 When a product made a claim about the absence or presence of a particular nutrient, further detailed
17 information was collected. The actual wording of the claim was noted and values in the NIP
18 information were recorded. This study did not attempt to survey the use of health claims on
19 products, that is statements that relate the nutrient content of a product to possible physiological or
20 health benefit.

21
22

23 ***Data Analysis***

24 All data were entered into a Microsoft Excel 98 database. They were analysed for:

- 25 1) number and type of products carrying nutrition claims, nutrition related claims or endorsements
- 26 2) the wording used to make nutrition claims
- 27 3) compliance of claims with current food regulations and reasons for non-compliance.

28
29 Compliance of claims for energy, fat, fibre, sodium/salt, sugar, energy, cholesterol, %free, light/lite,
30 diet and comparative claims were assessed against the criteria in COPONC. Claims for vitamins
31 and minerals were assessed for compliance with Standard A9 of the FSC1. Claims for protein were
32 assessed for compliance with Standard A1(14) of the FSC1.

1
2 Claims such as no added sugar and unsalted were not assessed for compliance since this could not
3 be determined by examination of information on the NIP. Such claims and those that are not
4 regulated (for example, claims related to carbohydrate) were recorded as being compliant.

5
6 Differences between the nutrient content of foods making claims to be a source or a good source of
7 protein were compared with Student t tests, using the SPSS Base 9.0 statistical program.

8

1 **Results**

2 A total of 6662 food products were surveyed. Table 3 summarises the number of products in each
3 of the 40 food categories, the number of nutrient and nutrition related claims made on products in
4 each category, and the percentage of products carrying any claims. Just over half of all products
5 surveyed (51.3%) carried some type of nutrition related claim and more than one third (36.2%)
6 carried at least one nutrient claim. Many products carried more than one claim, and over all food
7 categories the mean number of nutrition related claims was 1.2 per product.

8
9 Sports drinks carried the highest proportion of nutrient claims (97.4% of products) and a high
10 proportion was found in breakfast cereals (87.4%), meat substitutes (76.6%) pretzels and rice cakes
11 (75.6%), muesli bars (73.8%) and yoghurts (72.5%). The categories that featured the lowest
12 proportion of products with a nutrient claim were cooking sauces (12%), vegetables (8%), meat
13 products (7.7%) and olives (0%). Sports drinks also had the highest percentage of products with any
14 type of nutrition related claim (97.4%). Meat substitutes (95.3%), pretzels and rice crackers (92.7%)
15 and breakfast cereals (88.5%) also had high percentages of products with any nutrition related
16 claims. The categories with the fewest nutrition related claims were ice creams (25.2%), soft drinks
17 (21.6%), and olives (18.2%).

18
19 Table 4 shows the types of nutrition claims made for eight broad product categories. Over all
20 products the most common nutrient claim related to fat (18.2% of products) and cholesterol (9.1%).
21 Use of nutrient claims varied by product type. The foods with the highest frequency of use for each
22 nutrient claim were as follows: energy (52.6% sports drinks; 36% rices), protein (42.2% meat
23 substitutes; 34.8% canned beans), fat (60.7% breakfast cereals; 54.6% yoghurts), cholesterol
24 (69.9% edible oils; 68.8% meat substitutes), carbohydrate (51.9% breakfast cereals; 31.9% muesli
25 bars), sugar (37.9% juices; 29.6% canned fruit), fibre (57.4% breakfast cereals; 54.3% canned
26 beans), vitamin and minerals (50.3% breakfast cereals; 48.8% eggs), sodium (32% rice; 30.8% soup
27 mixes). The foods with the fewest nutrient claims were cordials, fresh meats, olives, and bottled and
28 canned vegetables (each with <10% carrying claims).

29
30 A high proportion of products carried nutrition related claims. “Preservative free” was found on
31 20.1% of all products and was used on more than 40% of canned foods, chips, juices, meat
32 substitutes, pretzels and rice cakes. “No artificial colours” was claimed on 17.6% of products and

1 “no artificial flavours” on 14.8%. Some other claims were common in specific food categories only.
2 Lactose free claims (used on 1.3% of products overall) were found on more than 20% of milk and
3 milk substitute products. Gluten free claims (2.7% of all products) were used on more than 30% of
4 rices and rice crackers. MSG free claims were used in more than 20% of all canned soups and chips
5 but only 2.9% of all products. GM free claims (1.7% of all products) were most prevalent on rice
6 (29.6%), milk and milk substitutes (14.8%) and meat substitutes (14.1%). Organic claims (1.1% of
7 products) were most common on eggs (23.3%), milk and milk substitutes (14.8%), meat substitutes
8 (14.1%) and meats (11.1%). Among other nutrition related claims only thirteen claimed foods were
9 wholegrain (4 breakfast cereals and 9 breads).

10
11 Endorsement of products by third party organisations was relatively uncommon. The Tick program
12 of the Heart Foundation [30] was by far the most common endorsement. It was used on 5.5% of all
13 products surveyed and was particularly prevalent on custards (36%), edible oils (27.2%), fat spreads
14 (26.8%), pretzels and rice cakes (19.5%), yoghurt (18.6%), breakfast cereals (18%), milk and milk
15 substitutes (14.3%), meat substitutes (14.1%) and breads (13.4%). None of the other endorsements
16 was widely used, although a few specific product categories commonly used other endorsements:
17 40.6% of meat substitutes were endorsed by the Vegetarian Society and 17% of muesli bars and
18 13.2% of sports drinks carried messages from the Sports Dietitians Association. Environmental
19 claims were restricted to eggs (32.6% claimed to be free range) and seafood (38.5% of canned fish
20 were labelled as dolphin friendly). Other endorsements (International Diabetes Institute, Heart
21 Research Institute, Kosher, Halal and the Australian Institute of Sport) were found on less than
22 0.5% of all products surveyed. The ANZFA logo endorsing a folate health claim was very rarely
23 used and found in only two product categories: 0.5% of breakfast cereals and 1.6% of meat
24 substitutes.

25
26 Table 5 summarises the wording and descriptors used to make nutrition claims. The most widely
27 used claims related to fat, cholesterol, vitamins and minerals, sugar and dietary fibre. A much
28 greater variety of descriptors was used than are defined in the FSC or COPONC. The most common
29 terms used were “free/no/zero” (16.7%), “% free” (14.1%), “source” (15%), “low” (10.9%) and
30 “high” (9.4%). A number of descriptors were used that are not defined within current regulations
31 (for example, “rich in”, “packed with”, “great source of”, “sustained”, “guaranteed”). There were

1 also a substantial number of products carrying claims for lycopene (n=100), phytoestrogens (n=43)
2 and glycemic index (GI) (n=15), yet none of these claims were included in the FSC or COPONC.

3
4 The number and percentage of claims that did not comply with either the FSC regulations or the
5 COPONC are set out in Table 6. Overall 12.9% of all nutrient claims failed to comply in some
6 manner with the mandatory or voluntary requirements. The types of claims most commonly non-
7 compliant were:

- 8 • Light/lite claims without a statement specifying the characteristic that was light (68.5%)
- 9 • Low or reduced saturated fat claims without a declaration of the content in the NIP (59.2%)
- 10 • Claims for reduced levels of a nutrient without a comparative statement of the reference food
11 and percentage reduction (25%)
- 12 • % fat free claims which did not include a statement in close proximity giving the percentage of
13 fat in the product (14.4%).

14
15 Approximately 5% of nutrient claims were non-compliant because they failed to meet the specified
16 nutritional criteria. However, there were five types of claims that had significantly higher levels of
17 non-compliance: 17.9% of cholesterol free claims were made on foods that were neither low in fat
18 nor low in saturated fat; 11.9% of high fibre claims appeared on foods that did not provide at least
19 3g fibre/serve; 11.8% of food claiming to provide a source of protein contained less than 5g per
20 serve, 11.1% of very high fibre claims were on foods that did not provide at least 6g fibre/serve and
21 10.2% of % fat free claims were used on foods that contained more than 3% fat. It should be noted
22 there were an additional 2.1% of all claims that were made without a declaration of the nutrient in
23 the NIP, which made it impossible to assess their compliance, so the total non-compliance rate
24 could be as high as 7.2%.

25
26 Table 7 compares the protein content of foods claiming to be a source or a good source of protein
27 (or words of similar meaning). Most (88.2 %) of the products met the FSC1 requirements for
28 making a claim (ie, providing at least 5g protein per serve and 12% energy from protein).
29 Paradoxically, those products claiming to be only a source of protein contained significantly
30 *higher* amounts of protein per 100g than those foods carrying claims that they were a good source
31 or high in protein (p = 0.002). When compared in grams of protein per serve or as a percentage of

- 1 energy from protein the differences between products with the different claims were not statistically
- 2 significant.
- 3

1 **Discussion**

2 As large as this survey was, because of time and resource limitations there were a number of major
3 categories of food that were not surveyed, including some frozen foods (vegetables, mixed meals
4 and fish), noodles, pasta, confectionery, canned meat, cake and bread mixes, flour, sugars and
5 syrups, dry beans, dried fruit, baby foods, spices and herbs, tea and coffee. Furthermore, even in the
6 categories surveyed it was not possible to obtain a complete census of all products in the
7 marketplace. This survey also excluded unpackaged food such as fresh fruit and vegetables and
8 bread rolls, although in some cases there may have been nutrition related claims made about those
9 products via in-store displays. Thus the quantitative results should be treated with some caution and
10 cannot be taken to represent all the foods currently available in Australia, which are now estimated
11 to number around 15,000 in a typical large supermarket. However it did attempt to include all the
12 leading products in a large range of food categories and therefore does provide a useful picture of
13 the use of nutrition claims in the Australian market in 2001 and indicates trends in their use.

14

15 *Prevalence and type of claims*

16 The total percentage of products carrying nutrient claims (36.2%) was comparable to the results
17 from a similar study conducted in 1997 by the FDA in the USA, which reported 38.7% of all
18 products sold carried a nutrient claim [31]. As was found here, that study reported that nutrient
19 claims about fat predominated (22.5% of all US products carried a fat claim, compared with 18.5%
20 in this study). Energy-related claims were the next most common category on claims in the US
21 (7.1% products), but not so in Australia where such claims were less common than those for
22 cholesterol, vitamins and minerals, sugar or fibre, and were found on only 3.8% of products.

23

24 The widespread use of nutrition claims in most food categories suggests that they are regarded as
25 important by food marketers and reflects the value that consumers place on such information. By
26 far the most popular nutrient claims related to fat content and type. The use of the term “%fat free”
27 was almost twice as common as use of the term “low fat”. The more quantitative nature of the
28 former may be appealing to marketers than the more general term and the use of the word “free”
29 may be seen as attractive to diet conscious consumers. While such claims can assist consumers to
30 choose foods in line with the Dietary Guidelines for Australians [32], there has been concern
31 expressed that people could wrongly assume that low fat and fat free products can be eaten freely,
32 without regard to their energy content and other nutritional characteristics. It is notable that in the

1 USA, although fat intake has declined as a percentage of energy over the past 25 years, the
2 prevalence of obesity has dramatically increased [33].

3
4 Claims relating to cholesterol were quite prevalent even though current nutritional advice places
5 much less importance on dietary cholesterol as a risk factor for cardiovascular disease and more
6 emphasis on fat type [34]. Cholesterol free claims were very commonly used, often on foods that
7 are naturally low in animal fats and cholesterol, such as breakfast cereals, beans, rice and soy
8 products. Cholesterol claims were also used on more than two thirds of all edible oil products.
9 Canadian studies report that most consumers rely on a no cholesterol claim to select a product
10 without further reference to the fat content [12]. The continued use of cholesterol claims may be
11 adding to confusion about the best nutritional advice and would often be misleading, especially
12 when about one in five such claims appeared on products that did not satisfy the criteria set out in
13 the COPONC requiring that the products should be low in fat or low in saturated fat.

14
15 The prevalence of nutrient claims did not always seem to be proportional to the importance of the
16 nutrients from a population health viewpoint. For example, the 1995 National Nutrition Survey
17 results suggest that Australians have adequate intakes of most vitamins, minerals and protein [35]
18 yet there were many more claims for these nutrients than for sodium, a nutrient that most
19 Australians overconsume [36]. Clear labelling of reduced salt products could assist consumers to
20 modify their intakes appropriately. It also seems clear that food manufacturers are using claims to
21 drive consumer interest and expectations about a number of bioactive substances which appear to
22 have potential health benefits (such as phytoestrogens and lycopene) ahead of national dietary
23 recommendations about their intakes.

24
25 Claims were made for a number of nutrients that are not currently regulated in the FSC or
26 COPONC, including carbohydrate and wholegrain. The limited number of wholegrain claims was
27 somewhat surprising, given emerging evidence for the benefits of increased wholegrain
28 consumption to reduce the risk of cardiovascular disease and some cancers [37, 38] and the fact that
29 such foods are recommended in the Australian dietary guidelines [32, 39, 40]. Manufacturers may
30 feel inhibited in making wholegrain claims by the narrow definition currently used in Standard
31 2.1.1(1) of the FSC2: “*wholegrain means the unmilled products of a single cereal or mixture of*

1 *cereals*". In the USA, processed foods are permitted to carry an FDA approved health claim about
2 wholegrain foods if they contain at least 51% by weight of any combination of whole grains [41].
3

4 One of the differences between the old and new versions of the FSC is that the definition of a
5 nutrient claim for protein is no longer regulated in FSC2. The results from this survey suggest that
6 there is a need to consider reinstatement of a definition for such claims and to define the criteria to
7 distinguish foods labelled as a source of protein from those claiming to be a good source or high in
8 protein, since there was no significant difference in the protein content of foods using these
9 different claims.
10

11 The survey found there was widespread use of claims about food additives. A number of Australian
12 studies have examined consumer attitudes to food additives [42-44]. In general between about a
13 quarter and a half of respondents in these surveys say they look for information on additives.
14 Similar trends have been reported in New Zealand where 55% of main householder shoppers
15 thought that a "no preservatives" claim was useful, even on a canned product that is not allowed to
16 have preservative added [45, 46]. This contrasts with the position on negative claims set out in the
17 food industry Code of Practice on the Provision of Information on Food Products, which
18 discourages the use of claims such as "no preservative", unless the consumer would normally
19 expect the substance to be present in the food [26]. The stated reason for this advice is not to
20 exacerbate consumers' negative views about additives and processed foods in general. Clearly from
21 the results of this survey, food manufacturers are largely ignoring this recommendation. Over 20%
22 of all product labels carried "preservative free" claims and the proportion was over 40% on canned
23 products, chips, pretzels and rice crackers, juices and meat substitutes.
24

25 ***Compliance with regulations***

26 There has only been one other published review of use of nutrient claims and their compliance with
27 the requirements of COPONC. In the 1997-98 Annual Report of the FCMC, a survey was reported
28 of 343 products in 20 food categories [47]. A total of 542 nutrient claims were assessed but no
29 quantitative results were presented. The report stated that there were "no apparent trends in non-
30 compliance" but did note that several products claimed "x% fat free" when they were not low fat
31 foods.
32

1 The majority (61%) of claims that failed to comply with regulations in this 2001 survey did so
2 because of breaches of requirements related to the format of labelling. In some cases these were
3 unlikely to cause any serious misrepresentation to the consumer. For example, according to the
4 requirement of COPONC, % fat free claims should be accompanied by a statement of the
5 percentage fat contained in the product, in close proximity. There has been very little research to
6 investigate whether such statements are useful to consumers. In most cases where this statement
7 was not given, the value was provided on the label in the NIP, so consumers would still be able to
8 compare the fat content of two products with the claim. However in one study with US adolescents,
9 participants were five times more likely to use front of label nutrition claims than the NIP when
10 making purchase decisions, so it may be important to provide the information on fat content close to
11 the nutrient claim [48].

12

13 Approximately 40% of the non-compliant claims (5.1% of all nutrient claims) were potentially
14 serious in that they did not meet the established nutritional criteria for the claim. Clearly these
15 instances could be classified as false and misleading, although in many cases the level of non-
16 compliance was relatively modest (eg, a product claiming to be high in fibre providing 2.9g fibre
17 per serve, instead of the required 3g). Claims that a food is a good source of a vitamin may be used
18 by consumers as a general reassurance of its overall health value, rather than being relied upon as a
19 guarantee of a specific amount of a nutrient, but there is no research that has attempted to measure
20 the impact of such incorrect claims on consumer purchases or overall nutrient intakes. Nonetheless,
21 the significant level of non-compliance poses a threat to the credibility of all claims and may
22 contribute to continuing consumer scepticism. Such scepticism is consistent with descriptions of the
23 coping tactics consumers employ generally when they believe that a persuasion attempt is occurring
24 [49, 50].

25

26 It is pertinent to note that more than 80% of the non-compliant claims related to requirements in the
27 voluntary COPONC. The levels of compliance with claims regulated by the FSC appeared much
28 higher and this may provide justification for making all regulations about nutrient claims mandatory
29 within the FSC, as has been recommended in the draft assessment report from ANZFA [28].

30

1 ***Endorsements***

2 While some qualitative research suggests consumers do not necessarily place great value on product
3 endorsements generally, those associated with health organisations do have some influence [20].
4 Consumers report using endorsements such as the Heart Foundation’s Tick to guide their food
5 purchasing choices [51] and use of the Tick does appear to encourage healthier choices as well as
6 improvements in the food supply [52, 53]. From this study it appeared that health endorsements
7 were mostly limited to only a few major food categories, especially those where consumers may be
8 uncertain about their nutritional qualities (eg, fat spreads, edible oils) or where they are marketed as
9 providing significant nutritional benefits (eg, sports drinks, breakfast cereals). The very low usage
10 of the ANZFA folate endorsement was notable, despite the fact that over 100 products were
11 approved to carry the claim and the logo [54]. This may be because companies were unconvinced of
12 the public recognition of ANZFA as an endorsing agency and preferred to use their own individual
13 marketing strategies [55].

14

15 ***Implications for the regulation of nutrition and related claims***

16 The results of this survey indicate widespread use of nutrition related claims on packaged food in
17 Australia. The range of claims was extensive, much broader than covered by the food standards and
18 the COPONC. A management framework for regulating nutrition and related claims would need to
19 consider the range of claims that manufacturers may wish to use. Current government and industry
20 guidance both fall short of comprehensive coverage. This situation is likely to become worse in the
21 future as new food components are identified and their role in nutrition established. Governments
22 need to consider the extent to which they can determine the validity and control the use of such
23 claims and to what extent should industry itself have responsibility for this, as currently is the case
24 with the use of equivalent level claims about complementary medicines in Australia [56].

25

26 However, a key to the balance between government and industry-based control is the likelihood of
27 compliance. The results of this survey indicate that the rate of non-compliance with both
28 government laws and industry guidelines is of concern. Non-compliance was highest with the
29 COPONC (80% of non-compliant claims) indicating that voluntary compliance is not likely to be
30 effective. Adoption of mandatory requirements for all claims within the Food Standards Code may
31 improve the levels of compliance.

32

1 Whether a regulatory or voluntary approach is taken, it is clear that enforcement mechanisms also
2 need to be in place to ensure compliance. In Australia, enforcement of the FSC is the responsibility
3 of State and Territory jurisdictions. Such a dispersed approach to enforcement may reduce its
4 effectiveness, due to duplication of effort and the resources needed to monitor the large number of
5 food products on the supermarket shelves. Industry enforcement of the COPONC is limited due to
6 its lack of legal power over its members. Guidance can be provided but compliance is still
7 voluntary. The model used in the complementary medicines area in Australia is a combination of
8 these two approaches. An independent council provides guidance and requests voluntary
9 compliance but if this is not adhered to, the Therapeutics Goods Administration (TGA) can step in
10 with legislative powers. Another possible enforcement model is that of an independent ombudsman
11 with the power to monitor and enforce compliance.

12
13 The range of claims and their frequency also raises issues of public health importance. Claims
14 currently on food labels do not fully reflect public health priorities. Some nutrients such as
15 cholesterol, vitamins and minerals, appear frequently on labels, while claims about other nutrients
16 of greater public health concern, such as sodium/salt, are far less frequent. A further consideration
17 is the impact on the use of claims on food labels that may result when food regulations are changed.
18 The results of this survey suggest that the regulations in FSC2 regarding claims for the key nutrients
19 protein and carbohydrate, and for the use of the term wholegrain, may need to be revisited to ensure
20 maximum public health benefit from use of such claims on food labels.

21
22 Claims about recently investigated components in foods (for example, lycopene and
23 phytoestrogens) and new nutritional concepts (glycemic index) also appear on food labels when
24 authoritative guidelines regarding their role in human nutrition are yet to be formulated. The
25 regulatory question is what is the role of such claims on food labels? Should the range of claims be
26 restricted to those that reflect and support (government agreed) public health nutrition messages
27 such as dietary guidelines? Or should the accepted range of claims be broader than this, allowing
28 manufacturers to promulgate new nutrition-related information to consumers via food labels, prior
29 to agreed public health messages being developed?

30

1 Finally, decisions regarding the role of nutrition and related claims on foods should be informed by
2 research examining the role of such claims on consumer purchasing and food consumption
3 behaviour. Such data are not currently available and research in this area is recommended.

| Other products (n = 1275) | 1.3 | 0.0 | 8.4 | 4.7 | 0.0 | 5.3 | 0.9 | 1.5 | 1.3 | 4.5 | 3.8 |
| All products (n = 6662) | 3.8 | 1.8 | 18.2 | 9.1 | 3.1 | 5.9 | 5.5 | 7.9 | 3.1 | 3.4 | 3.7 |

3

4 * Product categories defined as follows:

5 Cereal products – breads, breakfast cereals, biscuits, canned pasta, crumpets, muffins, muesli bars, pretzels, rice cakes, rice

6 Dairy products – milk, cheese, yoghurt, cream, custard, ice cream

7 Drinks – juices, cordials, soft drinks, sports drinks, drink bases

8 Vegetables and fruit – canned beans, canned fruit, canned and bottled vegetables, olives

9 Fats and oils – edible oils, fat spreads, salad dressings

10 Meat and substitutes – meats, processed meats, meat substitutes, seafood, eggs

11 Soups – canned soup, soup mixes

12 Other products – chips, cooking sauces, fruit bars, salsas, spreads, coconut milks

13

14 **Other = lycopene, GI, phytoestrogens, sterols, amino acids, antioxidants

15

3 * Not included in COPONC ** COPONC only permits %Free with fat

4 # Shaded columns are generally covered by the FSC, not by COPONC

5

1 **Table 6: Non-compliant nutrient claims (out of total of 4401 claims)**
 2

| Reason for non-compliance | Source of criteria | Number of non-compliant claims | Percentage of claims that are non-compliant |
|---|--------------------|--------------------------------|---|
| Claim does not meet defined nutritional criteria: | | | |
| <i>Cholesterol free</i> | COPONC | 105 | 17.9 |
| <i>% Fat free</i> | COPONC | 63 | 10.2 |
| <i>High fibre</i> | COPONC | 19 | 11.9 |
| <i>Source of protein</i> | FSC | 14 | 11.8 |
| <i>Low fat</i> | COPONC | 13 | 3.7 |
| <i>%RDI vitamin/serve</i> | FSC | 6 | 8.3 |
| <i>Good source of vitamin or mineral</i> | FSC | 3 | 2.3 |
| <i>Source of fibre</i> | COPONC | 1 | 0.7 |
| <i>Very high fibre</i> | COPONC | 1 | 11.1 |
| | | Total 225 | (5.1)* |
| Nutrient claim made but no values declared in NIP: | | | |
| <i>Gluten</i> | FSC | 27 | 9.6 |
| <i>Saturated fat</i> | FSC | 16 | 59.2 |
| <i>Cholesterol</i> | FSC | 13 | 2.1 |
| <i>Vitamin or mineral</i> | FSC | 13 | 1.8 |
| <i>DHA/Omega 3 fats</i> | FSC | 9 | 19.1 |
| <i>Light</i> | COPONC | 5 | 7.1 |
| <i>% Fat free</i> | COPONC | 4 | 0.6 |
| <i>Low fat</i> | COPONC | 3 | 0.9 |
| <i>Fibre</i> | COPONC | 2 | 0.5 |
| <i>Reduced fat</i> | COPONC | 1 | 1.2 |
| | | Total 93 | (2.1)* |
| % Fat free claim, without statement of % fat in close proximity | COPONC | 89 | 14.4 |
| Reduced claim, without required comparative statement of percent reduction and reference food | | | |
| <i>Fat</i> | COPONC | 54 | 55.7 |
| <i>Salt</i> | COPONC | 7 | 24.9 |
| <i>Sugar</i> | COPONC | 5 | 45.5 |
| <i>Energy</i> | COPONC | 1 | 1.5 |
| | | Total 67 | (25.0)** |
| Light/Lite claim, without a statement of the characteristic that is light | COPONC | 48 | 68.5 |
| Cholesterol free claim, but no reference to the whole class of similar foods | COPONC | 30 | 5.1 |
| Low fat claim, but no reference to the whole class of similar foods | COPONC | 7 | 2.0 |
| Low joule/Diet claim, without required statement of energy content | FSC | 7 | 6.1 |
| Total | | 566 | 12.9 |

3 * percentage of all nutrient claims that are non-compliant

4 ** percentage of all Reduced claims that are non-compliant

5

1 **Table 7: Protein content of products carrying protein nutrient claims (mean ± SD; range)**
 2

| Nutrient Claim | g protein per 100g | g protein per serve | % Energy from protein |
|--|----------------------------|----------------------------|------------------------------|
| <i>Source/Contains/Provides/Guaranteed</i> (n = 34) | 14.4 ± 6.7 (5.3 – 23.0) | 10.5 ± 5.1 (5.3 – 19.6) | 29.9 ± 13.7 (13.9 – 46.0) |
| <i>Good source/High/Rich/Extra</i> (n = 84) | 9.8 ± 7.0 (1.7 – 31.0) | 10.6 ± 4.3 (2.8 – 19.6) | 25.7 ± 9.8 (11.3 – 56.0) |
| Significance of difference (p =) | 0.002 | 0.930 | 0.105 |
